

# Current Mode PWM Control Circuit

## Description

The CS52843 provides all the necessary features to implement off-line fixed frequency current-mode control with a minimum number of external components.

The CS52843 incorporates a new precision temperature-controlled oscillator to minimize variations in frequency. An undervoltage lock-out ensures that  $V_{REF}$  is stabilized

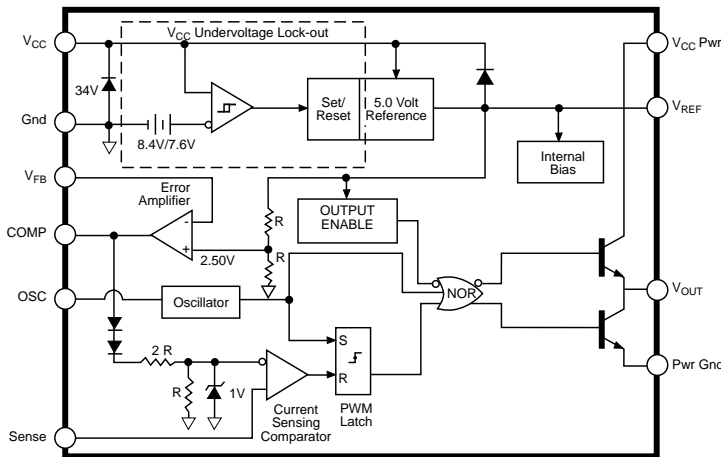

before the output stage is enabled. In the CS52843 turn on is at 8.4V and turn off at 7.6V.

Other features include low start-up current, pulse-by-pulse current limiting, and a high-current totem pole output for driving capacitive loads, such as gate of a power MOSFET. The output is low in the off state, consistent with N-channel devices.

Circuit Description

Figure 1: Startup voltage for the CS52843.

Undervoltage Lockout

During Undervoltage Lockout (Figure 1), the output driver is biased to sink minor amounts of current. The output should be shunted to ground with a resistor to prevent activating the power switch with extraneous leakage currents.

PWM Waveform

To generate the PWM waveform, the control voltage from the error amplifier is compared to a current sense signal which represents the peak output inductor current (Figure 2). An increase in  $V_{CC}$  causes the inductor current slope to increase, thus reducing the duty cycle. This is an inherent feed-forward characteristic of current mode control, since the control voltage does not have to change during changes of input supply voltage.

When the power supply sees a sudden large output current increase, the control voltage will increase allowing the duty cycle to momentarily increase. Since the duty cycle tends to exceed the maximum allowed to prevent transformer saturation in some power supplies, the internal oscillator waveform provides the maximum duty cycle clamp as programmed by the selection of oscillator timing components.

Figure 2: Timing Diagram

### Setting the Oscillator

The times T<sub>c</sub> and T<sub>d</sub> can be determined as follows:

$$t_c = R_T C_T \ln \left( \frac{V_{REF} - V_{LOWER}}{V_{REF} - V_{UPPER}} \right)$$

$$t_d = R_T C_T \ln \left( \frac{V_{REF} - I_d R_T - V_{LOWER}}{V_{REF} - I_d R_T - V_{UPPER}} \right)$$

Substituting in typical values for the parameters in the above formulas:

V<sub>REF</sub> = 5.0V, V<sub>UPPER</sub> = 2.7V, V<sub>LOWER</sub> = 1.0V, I<sub>d</sub> = 8.3mA, then

$$t_c \approx 0.5534 R_T C_T$$

$$t_d = R_T C_T \ln \left( \frac{2.3 - 0.0083 R_T}{4.0 - 0.0083 R_T} \right)$$

For better accuracy R<sub>T</sub> should be ≥10kΩ.

### Grounding

High peak currents associated with capacitive loads necessitate careful grounding techniques. Timing and bypass capacitors should be connected close to Gnd in a single point ground.

The transistor and 5kΩ potentiometer are used to sample the oscillator waveform and apply an adjustable ramp to Sense.
