

- Easy Evaluation for the SP6136ER1 12V Input, 0 to 7A Output Synchronous Buck Converter
- Precision 0.80V  $\pm$ 1% High Accuracy Reference
- Small form factor
- Feature Rich: Single supply operation, Over-current protection with auto-restart, Power Good Output, Enable input, Fast transient response, Short Circuit Shutdown Protection, Programmable soft start
- TSSOP Package & SMT components for small, low profile Power Supply

### SP6136EB SCHEMATIC

**1) Powering Up the SP6136EB Circuit**

Connect the SP6136ER1 Evaluation Board with an external +12V power supply. Connect with short leads and large diameter wire directly to the “VIN” and “GND” posts. Connect a Load between the “VOUT” and “GND2” posts, again using short leads with large diameter wire to minimize inductance and voltage drops.

**2) Measuring Output Load Characteristics**

It's best to GND reference scope and digital meters using the Star GND post in the center of the board. VOUT ripple can best be seen touching probe tip to the pad for COUT and scope ground collar touching Star GND post – avoid a ground lead on the probe which will increase noise pickup.

**3) Using the Evaluation Board with Different Output Voltages**

While the SP6136ER1 Evaluation Board has been tested and delivered with the output set to 3.30V, by simply changing one resistor, R2, the SP6136ER1 can be set to other output voltages. The relationship in the following formula is based on a voltage divider from the output to the feedback pin VFB, which is set to an internal reference voltage of 0.80V.

Standard 1% metal film resistors of surface mount size 0603 are recommended.

$$V_{out} = 0.80V \left( \frac{R1}{R2 + 1} \right) \Rightarrow \\ R2 = R1 / \left[ \left( \frac{V_{out}}{0.80V} \right) - 1 \right]$$

Where  $R1 = 68.1K\Omega$  and for  $V_{out} = 0.80V$  setting, simply remove R2 from the board. Furthermore, one could select the value of

the R1 and R2 combination to meet the exact output voltage setting by restricting R1 resistance range such that  $50K\Omega \leq R1 \leq 100K\Omega$  for overall system loop stability.

Note that since the SP6136ER1 Evaluation Board design was optimized for 12V down conversion to 3.30V, changes of output voltage and/or input voltage may alter performance from the data given in the Power Supply Data section.

**POWER SUPPLY DATA**

The SP6136ER1 is designed with an accurate 1.5% reference over line, load and temperature. Figure 1 data shows a typical SP6136ER1 Evaluation Board efficiency plot, with efficiencies to 92% and output currents to 7A. Load Regulation in Figure 2 shows only 0.12% change in output voltage from no load to 7A. Figures 3 and 4 show the fast transient response. Start-up corresponding to different load conditions is shown in Figures 5, 6 and 7, where the input current rises smoothly as the soft-start ramp increases. In Figure 8 the hiccup mode gets activated in response to an output dead short circuit condition and will soft-start until the over-load is removed. Figure 9 and 10 show output voltage ripple less than 11mV over complete load range.

While data on individual power supply boards may vary, the capability of the SP6136ER1 of achieving high accuracy over a range of load conditions shown here is quite impressive and desirable for accurate power supply design.

## LOOP COMPENSATION DESIGN

The open loop gain of the SP6136EB can be divided into the gain of the error amplifier **GAMP(s)**, PWM modulator **GPWM**, buck converter output stage **GOUT(s)**, and feedback resistor divider **GFBK**. In order to crossover at the selected frequency **fc**, the gain of the error amplifier has to compensate for the attenuation caused by the rest of the loop at this frequency. The goal of loop compensation is to manipulate the open loop frequency response such that its gain crosses over 0dB at a slope of  $-20\text{dB/dec}$ . The open loop crossover frequency should be higher than the ESR zero of the output capacitors but less than  $1/5$  of the switching frequency **fs** to insure proper operation. Since the SP6136EB is designed with ceramic type output capacitors, a Type III compensation circuit is required to give a phase boost of  $180^\circ$  in order to counteract the effects of the output **LC** under damped resonance double pole frequency.

### Definitions:

Resr := Output Capacitor Equivalent Series Resistance

Rdc := Output Inductor DC Resistance

Vramp\_pp := SP6134 Internal RAMP Amplitude Peak to Peak Voltage

### Conditions:

$Cz2 \gg Cp1$  and  $R1 \gg Rz3$

Output Load Resistance  $\gg$  Resr and Rdc

Figure 11. SP6136EB Voltage Mode Control Loop with Loop Dynamic

The simple guidelines for positioning the poles and zeros and for calculating the component values for Type III compensation are as follows:

$$R1 = 68.1K$$

$$R2 = \frac{0.8 \times R1}{V_{out} - 0.8} \quad (\text{sets output voltage})$$

$$CZ3 = \frac{1}{ZSF \times R1 \times \frac{1}{\sqrt{LC}}} \quad (\text{sets first zero})$$

$$RZ2 = \frac{\left( (6.28 \times fc)^2 \times L \times C_{out} \right) + 1}{6.28 \times fc \times CZ3} \times \frac{V_{ramp}}{V_{in}} \quad (\text{sets the cross-over frequency, } fc)$$

$$CZ2 = \frac{1}{ZSF \times RZ2 \times \frac{1}{\sqrt{LC}}} \quad (\text{sets second zero})$$

$$CP1 = \frac{1}{6.28 \times f_s \times RZ2} \quad (\text{sets first high-frequency pole})$$

$$RZ3 = \frac{1}{6.28 \times f_s \times CZ3} \quad (\text{sets second high-frequency pole})$$

Where  $ZSF = (f \text{ compensation double zero}) / (f \text{ circuit double pole})$   
 Here ZSF is set at 0.8.

As a particular example, consider for the following SP6136EB, 7AMAX with a type III Voltage Loop Compensation component selections:

$$V_{in} = 12V$$

$$V_{out} = 3.30V \text{ @ } 0 \text{ to } 7A \text{ load}$$

Select  $L = 2.2 \mu H \Rightarrow 30\%$  current ripple.

Select  $C_{out} = 100\mu F$  Ceramic capacitor ( $R_{esr} \approx 5m\Omega$ )

$f_s = 600KHz$  SP6136ER1 internal Oscillator Frequency

$V_{ramp\_pp} = 1.0V$  SP6136ER1 internal Ramp Peak to Peak Amplitude

**Step by step design procedures:**

- a. **R2** = 21.8k $\Omega$
- b. **CZ3** = 272pF
- c. **Let fc** =80kHz then:
- d. **RZ2** = 34.4k $\Omega$
- e. **CZ2** = 538pF
- f. **CP1** = 7.7pF
- g. **RZ3** = 0.97k $\Omega$
- h. **CF1** = 22pF to stabilize SP6136ER1 internal Error Amplify

The above component values were used as a starting point for compensating the converter and after laboratory testing the values shown in circuit schematic of page 1 were used for optimum operation.

**Figure 12- Gain/Phase measurement of SP6136EB shown on page 1, cross-over frequency (fc) is 85KHz with a corresponding phase of 65 degrees**
