## Conventions

The following notations and terminology are used in this manual. The Glossary defines all terms with special meanings.
\# The pound symbol (\#) has either of two meanings, depending on the context. When used with a signal name, the symbol means that the signal is active low. When used in an instruction, the symbol prefixes an immediate value in immediate addressing mode.
italics

XXXX

## Instructions

Logic 0 (Low)

Logic 1 (High)

Numbers

Register Bits

Assert and Deassert The terms Assert and Deassert refer to the act of making a signal active (enabled) and inactive (disabled), respectively. The active polarity (high/low) is defined by the signal name. Active-low signals are designated by a pound symbol (\#) suffix; active-high signals have no suffix. To assert RD\# is to drive it low; to assert ALE is to drive it high; to deassert RD\# is to drive it high; to deassert ALE is to drive it low.
Italics identify variables and introduce new terminology. The context in which italics are used distinguishes between two possible meanings.
Variables in registers and signal names are commonly represented by x and $y$, where $x$ represents the first variable and $y$ represents the second variable. For example, in register Px.y, x represents the variable that identifies the specific port, and y represents the register bit variable [7:0]. Variables must be replaced with the correct values when configuring or programming registers or identifying signals.

Uppercase X (no italics) represents an unknown value or a "don't care" state or condition. The value may be either binary or hexadecimal, depending on the context. For example, 2XAFh (hex) indicates that bits 11:8 are unknown; 10 XXb in binary context indicates that the two Least Significant Bits are unknown.

Instruction mnemonics are shown in upper case to avoid confusion. You may use either upper case or lower case.

An input voltage level equal to or less than the maximum value of $\mathrm{V}_{\mathrm{IL}}$ or an output voltage level equal to or less than the maximum value of $\mathrm{V}_{\mathrm{OL}}$. See Product Datasheet for values.

An input voltage level equal to or greater than the minimum value of $\mathrm{V}_{\mathrm{IH}}$ or an output voltage level equal to or greater than the minimum value of $\mathrm{V}_{\mathrm{OH}}$. See Product Datasheet for values.

Hexadecimal numbers are represented by a string of hexadecimal digits followed by the letter h. Decimal and binary numbers are represented by their customary notations: i.e. 255 is a decimal number and 11111111 is a binary number. In most cases of binary numbers, the letter b is added for clarity.

Bit locations are indexed by 7:0 for byte registers, 15:0 for word registers, and 31:0 for double word (dword) registers. Bit 0 is the least significant bit

| Register Names | Register names are shown in upper case. For example, PCON is the Power <br> Control register. If a register name contains a lowercase character, it <br> represents more than one register. For example, CCAPMx (x $=0,1,2,3,4)$ <br> represents the five registers: CCAPM0 through CCAPM4. |
| :--- | :--- |
| Reserved Bits | Some registers contain reserved bits. These bits are not used in this device <br> but they may be used in future implementations. Pay attention to the <br> recommendations when manipulating theses bits. |
| Set and Clear | The terms Set and Clear refer to the value of a bit or the act of giving it a <br> value. If a bit is Set, its value is " ""; setting a bit gives it a " " value. If a bit <br> is Clear, its value is " " 0 "; clearing a bit gives it a " 0 " value. |

## Introduction

### 1.1. 8/16-bit microcontroller

In the world of 8/16-bit microcontrollers, the C51 Architecture has become an industry standard for embedded applications. For over 15 years, Temic has been a leading provider of this microcontroller family. This unsurpassed experience is the driving force as TEMIC takes this proven family to the next level of performance: the TSC80251 family!
This new C251 Architecture at its lowest performance level (binary mode), is binary code compatible with the 80C51 microcontrollers, hence, attaining an increase in performance has never been easier.

Due to a 3-stage pipeline, the CPU-performance is increased by a factor 5, using existing C51 code without modifications.
Using the new C251 instruction set, which you will find in this document (See Chapter 5), the performance will increase up to 15 times at the same clock rate. This performance enhancement is based on the 16-bit instruction bus, allowing for more powerful instructions and additional internal instruction bus, 8 -bit and 16 -bit data busses.
The 24-bit address bus will allow to access up to 16 Mbytes in a single linear memory space. Please see each individual TSC80251 Product Design Guide for the effective addressable memory range.

Programming flexibility and C-code efficiency are both increased through a Register-based Architecture, the 64-Kbyte extended stack space combining with the new instruction set.
C251 C-compilers are some of the most efficient available (nearly no overhead), coupled with the final codesize which could be a factor of 3 down when compared with the C51 C-compilers.
All technical information in this document about core features are related to the core revision A and core revision D .

### 1.2. TSC80251 Derivatives

TEMIC is developing a full family of application specific TSC80251 derivatives. Please see the Design Guide of each product for further information.
These products are designed to help you getting high-performance products to market faster.
Due to the high instruction throughput, the TSC80251 derivatives are focussing on all high-end 8-bit to 16-bit applications.

TSC80251 derivatives are also used in mid-range and lower-end microcontroller applications, where a very low operation frequency is needed, without decreasing the level of CPU-power.
This feature is ideal for today portable applications and EMC sensitive systems.

Typical applications for this family are:

- Automotive:
- Airbag
- ABS
- Gearbox
- Climate control
- Car radio
- Car navigation
- Communication:
- Cordless phones
- Cellular phones
- High speed modems
- High-end feature phones
- ISDN phones
- Line cards
- Network termination
- Computer:
- High-end monitors
- DVD-ROM
- Magtape card \& smart card readers
- Barcodes readers
- Computer telephony
- Force feedback joysticks
- Industrial:
- Process monitoring control \& readouts
- Air conditioning systems
- Automation

TEMIC's TSC80251 derivatives are designed around the C251 core, using standard peripherals dedicated to a targetted range of applications.
Here is a selection of peripheral blocks:

- Serial interfaces:
- UART (Universal Asynchronous Receiver Transmitter)
- I2C (Inter-Integrated Circuit)
- SPI (Serial Protocol Interface)
- $\mu$ Wire (Synchronous Serial Interface)
- Special Functions:
- PCA: Programmable Counter Array ( $5 \times 16$-bit modules)
- High-speed output
- Compare/Capture I/O
- 8-bit Pulse Width Modulator (PWM)
- ADC (Analog to Digital Converter)
- Smart sensor interfaces with PMU (Pulse Measurement Unit)
- Control functions:
- Watchdog Timer
- Timers/Counters
- Power monitoring and management
- Interrupt handler
- Memories:
- RAM
- ROM
- EPROM/OTPROM

Most of TEMIC's TSC80251 derivatives are available as ROMless, OTPROM, EPROM and Mask ROM version. For any special request, refer to Temic sales representative.

Semiconductors

### 1.3. TSC80251 Documentation

The following documentation and starter tools are available to allow the full evaluation of the TEMIC's TSC80251 derivatives:

- "TSC80251 Programmer's Guide" Contains all information for the programmer (Architecture, Instruction Set, Programming).
- "TSC80251 Design Guide"

Contains all product specific data and a summary of available application notes.

- Application Notes
- "TSC80251 Product Starter Kit" This kit enables the product to be evaluated by the designer. Its contents is:
- C-Compiler (limited to 2 Kbytes of code)
- Assembler
- Linker
- Product Simulator
- TSC80251 Product Evaluation Board with ROM-Monitor
- EPROM and ROMless samples of the available derivatives
- Please visit our WWW for updated versions in ZIP format.
- World Wide Web

Please contact our WWW for possible updated information at http://www.temic-semi.com

- Technical support: C251 @temic-semi.com

## Architectural Overview

### 2.1. Microcontroller Architecture

The TSC80251 family of 8/16-bit microcontrollers is a high performance upgrade of the widely used 80C51 microcontrollers. It extends features and performance while maintaining binary code compatibility, so the impact on existing hardware and software is minimal.

The C251 Architecture core contains:

- 24-bit linear addressing and up to 16 Mbytes of memory
- a register file based CPU with registers accessible as bytes, words, and double words
- a page mode for accelerating external instruction fetches
- an instruction pipeline
- an enriched instruction set, including 16-bit arithmetic and logic instructions
- a 64-Kbyte extended stack space
- a minimum instruction-execution time of two clocks (vs. 12 clocks for 80C51 microcontrollers)
- binary-code compatibility with 80C51 microcontrollers

Several benefits are derived from these features :

- preservation of code written for 80C51 microcontrollers
- a significant increase in core execution speed in comparison with 80C51 microcontrollers at the same clock rate
- support for larger programs and more data
- increased efficiency for code written in C language

Figure 2.1. is a functional block diagram of TSC80251 microcontrollers. The core, which is common to all TSC80251 microcontrollers, is described in the next paragraph. Each derivative in the family has its own on-chip peripherals, I/O Ports, external bus, size of on-chip RAM, type and size of on-chip ROM.

Figure 2.1. TSC80251 Product Block Diagram

### 2.2. Microcontroller Core

The TSC80251 microcontroller core contains the CPU, the clock and reset unit, the interrupt handler, the bus interface and the peripheral interface (See Figure 2.1.). The CPU contains the instruction sequencer, ALU, register file and data memory interface (See Figure 2.2. ).

### 2.2.1. CPU

The TSC80251 fetches instructions from on-chip code memory two bytes at a time or from external memory one byte at a time. The instructions are sent over the 16-bit instruction bus to the CPU. You can configure the TSC80251 to operate in page mode for accelerated instruction fetches from external memory. In page mode, if an instruction fetch is to the same 256-byte "page" as the previous fetch, the fetch requires one state (two clocks) rather than two states (four clocks). For information regarding the page or non-page mode selection, see Product Design Guide.

The TSC80251 register file has 40 registers, which can be accessed as bytes (8-bit data), words (16-bit data) and double words (32-bit data). As in the C51 Architecture, registers 0-7 consist of four banks of eight registers each, where the active bank is selected by the Program Status Word (PSW) for fast context switches (See "Programming" chapter).

The TSC80251 CPU is a pipeline machine. When the pipeline is full and code is executing from on-chip code memory, an instruction can be completed every state time. When the pipeline is full and code is executing from external memory (with no wait states and no extension of the ALE signal) an instruction can be completed every two state times.

Figure 2.2. Central Processor Unit Block Diagram

### 2.2.2. Clock and Reset Unit

The timing source for the TSC80251 microcontroller can be an external oscillator or an internal oscillator with an external crystal/resonator. The basic unit of time in TSC80251 is the state time (or state), which is two oscillator periods. The state time is divided into phase P1 and phase P2 (See Figure 2.3. ).

Figure 2.3. Clocking Definitions
The TSC80251 peripherals operate on a peripheral cycle, which is six state times (this peripheral cycle is not a characteristic of the C251 Architecture). A one-clock interval in a peripheral cycle is denoted by its state and phase (SxPy). For simplicity purpose, XTAL1 signal has been used in this figure. In fact this is the prescaler output that drives the core. The clock prescaler being a software programmable device, the effective core clock can be dynamically adapted to the application speed and power consumption needs.
The reset unit places the TSC80251 into a known state. A chip reset is initiated by asserting the RST pin or allowing the Watchdog Timer to time out when the TSC80251 has one.

### 2.2.3. Interrupt Handler Unit

The Interrupt Handler Unit can receive interrupt requests from many sources: internal peripheral sources, external sources and TRAP instruction. When the interrupt handler grants an interrupt request, the CPU discontinues the normal flow of instructions and branches to a routine that services the source that requested the interrupt. You can enable or disable the interrupts individually (except for TRAP and NMI which cannot be disabled) and you can chose among one to four priority levels for each interrupt.

## Address Spaces

TSC80251 microcontrollers have three address spaces: a memory space, a Special Function Register (SFR) space and a register file. This chapter describes these address spaces as they apply to all TSC80251 microcontrollers. It also discusses the compatibility of the C251 Architecture and the C51 Architecture in terms of their address spaces.

### 3.1. C251 Architecture Address Spaces

Figure 3.1. shows the three address spaces: i.e. memory space, SFR space and register file for TSC80251 microcontrollers. The address spaces are depicted as being 8 -byte wide with addresses increasing from left to right and from bottom to top (See Figure 3.1. ).

Memory Address Space
16 Mbytes

Figure 3.1. Address Spaces for TSC80251 Microcontrollers

It is convenient to view the unsegmented, 16-Mbyte memory space as consisting of 256 64-Kbyte regions, numbered 00: to FF:

## Note :

The memory space in the C251 Architecture is unsegmented. The $64-$ Kbyte "region" 00:, 01., ..., FF: are introduced only as a convenience for discussions. Addressing in the C251 Architecture is linear; there are no segment registers.
TSC80251 microcontrollers can have up to $64-$ Kbytes of on-chip code memory in region FF:. On-chip data RAM begins at location 00:0000h. The first 32 bytes ( $00: 0000 \mathrm{~h}-00: 001 \mathrm{Fh}$ ) provide storage for a part of the register file.The sizes of the on-chip code memory and on-chip RAM depend on the particular device.

The register file has its own address space (See Figure 3.1.). The 64 locations in the register file are numbered decimally from 0 to 63. Locations $0-7$ represent one of four, switchable register banks, each having 8 registers. The 32 bytes required for these banks occupy locations 00:0000h-00:001Fh in the memory space. Register file locations 8 -63 do not appear in the memory space and are new hardware resources of the C251 Architecture.

The SFR space can accommodate up to 512 8-bit Special Function Registers with addresses S:000h-S:1FFh. Some of these locations may be unimplemented in a particular device. In the C251 Architecture, the prefix " S :" is used with SFR addresses to distinguish them from the memory space addresses 00:0000h-00:01FFh.

### 3.2. C51 Architecture Address Spaces

Figure 3.2. shows the address spaces of the C51 Architecture. Internal data memory locations 00h-7Fh can be addressed directly, indirectly by register addressing mode and bit addressing mode for data locations 20h-2Fh. Internal data locations 80 h -FFh can only be addressed indirectly. Directly addressing these locations accesses the SFRs. The 64-Kbyte code memory has a separate memory space. Data in the code memory can be accessed only with the MOVC instruction. Similarly, the 64-Kbyte external data memory can be accessed only with the MOVX instruction.
The register file (registers R0-R7) comprises four, switchable register banks, each having 8 registers. The 32 bytes required for the four banks occupy locations $00 \mathrm{~h}-1 \mathrm{Fh}$ in the on-chip data memory.

Figure 3.2. Address Spaces for the C51 Architecture

### 3.3. C51 Architecture mapping to C251 Architecture Address Spaces

The 64-Kbyte code memory for 80C51 microcontrollers maps into region FF: of the memory space for TSC80251 microcontrollers. Assemblers for TSC80251 microcontrollers assemble code for 80C51 microcontrollers into region FF:, and data accesses to code memory (MOVC) are directed to this region. The assembler also maps the interrupt vectors to region FF:. This mapping is transparent to the user; code executes just as with a 80C51 micro without modification.

Table 3.1. Address Mappings

| Memory Type | C51 Architecture |  |  | C251 Architecture |
| :--- | :--- | :--- | :--- | :--- |
|  | Size | Location |  | Data Addressing |
| Code | 64 Kbytes | $0000 \mathrm{~h}-$ FFFFh | Indirect using MOVC | FF:0000h-FF:FFFFh |
| External Data | 64 Kbytes | $0000 \mathrm{~h}-$ FFFFh | Indirect using MOVX | $01: 0000 \mathrm{~h}-01: \mathrm{FFFFh}$ |
| Internal Data | 128 bytes | $00 \mathrm{~h}-7 \mathrm{Fh}$ | Direct, Indirect | $00: 0000 \mathrm{~h}-00: 007 \mathrm{Fh}$ |
|  | 128 bytes | $80 \mathrm{~h}-\mathrm{FFh}$ | Indirect | $00: 0080 \mathrm{~h}-00: 00 \mathrm{FFh}$ |
|  | 128 bytes | S:80h-S:FFh | Direct | S:0080h-S:0FFh |
| Register | 8 bytes | R0-R7 | Register | $00: 0000 \mathrm{~h}-00: 001 \mathrm{Fh}$ |

The 64-Kbyte external data memory for 80C51 microcontrollers is mapped into the memory region specified by bits 16-23 of the data pointer DPX, i.e., DPXL, which is accessible as register file location 57 and also as SFR at S:084h. The reset value of DPXL is 01 h , which maps the external memory to region 01: as shown in Figure 3.3. You can change this mapping by writing a different value to DPXL. A mapping of the C51 Architecture external data memory into any 64-Kbyte memory region in the C251 Architecture provides complete runtime compatibility because the lower 16 address bits are identical in both architectures.

The 256 bytes of on-chip data memory for 80C51 microcontrollers (00h-FFh) are mapped to addresses 00:0000h-00:00FFh to ensure complete runtime compatibility. In the C51 Architecture, the lower 128 bytes ( $00 \mathrm{~h}-7 \mathrm{Fh}$ ) are directly and indirectly addressable; however the upper 128 bytes are accessible by indirect addressing only. In the C251 Architecture, all locations in region 00: are accessible by direct, indirect, and displacement addressing.

The 128-byte SFR space for 80C51 microcontrollers is mapped into the 512-byte SFR space of the C251 Architecture starting at address S:080h, as shown in Figure 3.3. This provides complete compatibility with direct addressing of 80C51 microcontroller SFRs (including bit addressing). The SFR addresses are unchanged in the new Architecture. In the C251 Architecture, SFRs, A, B, DPL, DPH and SP, as well as the new DPXL and SPH, reside in the register file for high performance. However, to maintain compatibility, they are also mapped into the SFR space at the same addresses as in the C51 Architecture.

Figure 3.3. Mappings C51 Architecture to C251 Architecture Address Spaces
Figure 3.4. TSC80251 Memory Space

### 3.4. TSC80251 Register File

The TSC80251 register file consists of 40 byte locations: $0-31$ and 56-63, as shown in Figure 3.5. These locations are accessible as bits, bytes, words and dwords. Several locations are dedicated to special registers; the others are general-purpose registers.
Register file locations 0-7 actually consist of four switchable banks of eight registers each, as illustrated in Figure 3.6. The four banks are implemented as the first 32 bytes of on-chip RAM and are always accessible as locations 00:0000h-00:001Fh in the memory address space. Only one of the four banks is accessible via the register file at a given time. The accessible, or "active", bank is selected by bits RS1 and RS0 in the PSW register, as shown in Table 3.2. This bank selection can be used for fast context switches.

Register file locations 8-31 and 56-63 are always accessible. These locations are implemented as registers in the CPU. Register file locations 32-55 are reserved and cannot be accessed.

Table 3.2. Register Bank Selection

| Bank | Address Range | PSW Selection Bits |  |
| :--- | :--- | :---: | :---: |
|  |  | RS1 | RS0 |
| Bank 0 | $00 \mathrm{~h}-07 \mathrm{~h}$ | 0 | 0 |
| Bank 1 | 08h-0Fh | 0 | 1 |
| Bank 2 | $10 \mathrm{~h}-17 \mathrm{~h}$ | 1 | 0 |
| Bank 3 | $18 \mathrm{~h}-1 \mathrm{Fh}$ | 1 | 1 |

### 3.4.1. Byte, Word and Dword Registers

Depending on its location in the register file, a register is addressable as a byte, a word, or a dword, as shown in the right side of Figure 3.5. A register is named for its lowest numbered byte location. For instance:

- R4 is the byte register consisting of location 4.
- WR4 is the word register consisting of registers 4 and 5 .
- DR4 is the dword register consisting of registers 4, 5, 6, and 7 .

Locations R0-R15 are addressable as bytes, words or dwords. Locations 16-31 are addressable only as words or dwords. Locations 56-63 are addressable only as dwords. Registers are addressed only by the names shown in Figure 3.5. , except for the 32 registers that comprise the four banks of registers R0-R7, which can also be accessed as locations 00:0000h-00:001Fh in the memory space.

Register File

| 56 | 57 | 58 | 59 | 60 | 61 | 62 | 63 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Locations 32-55 are Reserved |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |
| 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
| 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 |
| 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |

Byte Registers

| Register |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Note : |  | $\begin{aligned} & \mathrm{R} 10=\mathrm{B} \\ & \mathrm{R} 11=\mathrm{A} \end{aligned}$ |  |  |  |  |  |
| R8 | R9 | R10 | R11 | R12 | R13 | R14 | R15 |
| R0 | R1 | R2 | R3 | R4 | R5 | R6 | R7 |

| Word Registers |  |  |  |
| :---: | :---: | :---: | :---: |
| WR24 | WR26 | WR28 | WR30 |
| WR16 | WR18 | WR20 | WR22 |
| WR8 | WR10 | WR12 | WR14 |
| WR0 | WR2 | WR4 | WR6 |

Dword Registers

| DR56 = DPX | DR60 $=$ SPX |
| :---: | :---: |
|  |  |
| DR24 | DR28 |
| DR16 | DR20 |
| DR8 | DR12 |
| DR0 | DR4 |

Figure 3.5. Register File in Byte, Word, and Dword Register Views

Figure 3.6. Register File Locations 0-7

### 3.4.2. Dedicated Registers

The register file has four dedicated registers :

- R10 is the B -register.
- R11 is the accumulator (A).
- DR56 is the extended data pointer, DPX.
- DR60 is the extended stack pointer, SPX.

These registers are located in the register file; however, R10, R11 and some bytes of DR56 and DR60 are also accessible as SFRs. The bytes of DPX and SPX can be accessed in the register file only by addressing the dword registers. The dedicated registers in the register file and their corresponding SFRs are illustrated in Figure 3.7. and listed in Table 3.3.

Table 3.3. Dedicated Registers in the Register File and their Corresponding SFRs

| Register File |  |  |  |  |  | SFRs |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Name |  |  | Mnemonic | Reg. | Location | Mnemonic | Address |
| Stack Pointer (SPX) |  | - | - | DR60 | 60 | - | - |
|  |  | - | - |  | 61 | - | - |
|  | Stack Pointer, High |  | SPH |  | 62 | SPH | S:BEh |
|  | Stack Pointer, Low |  | SP |  | 63 | SP | S:81h |
| Data Pointer(DPX) |  | - | - | DR56 | 56 | - | - |
|  | Data Pointer, Extended Low |  | DPXL |  | 57 | DPXL | S:84h |
|  | DPTR | Data Pointer, High | DPH |  | 58 | DPH | S:83h |
|  |  | Data Pointer, Low | DPL |  | 59 | DPL | S:82h |
| Accumulator (A Register) |  |  | A | R11 | 11 | A | S:E0h |
| B Register |  |  | B | R10 | 10 | B | S:F0h |

### 3.4.2.1. Accumulator and B Register

The 8-bit accumulator (A) is byte register R11, which is also accessible in the SFR space as A at S:0E0h (See Figure 3.7. ). The B register, used in multiplies and divides, is register R10, which is also accessible in the SFR space as B at $\mathrm{S}: 0 \mathrm{~F} 0 \mathrm{~h}$. Accessing A or B as a register is one state faster than accessing them as SFRs.

Instructions in the C51 Architecture use the accumulator as the primary register for data moves and calculations. however, in the C251 Architecture, any of registers R1-R15 can serve for these tasks. As a result, the accumulator does not play the central role that it has in 80C51 microcontrollers.

### 3.4.2.2. Extended Data Pointer, DPX

Dword register DR56 is the extended data pointer, DPX (See Figure 3.7. ). The lower three bytes of DPX (DPL, DPH and DPXL) are accessible as SFRs. DPL and DPH comprise the 16-bit data pointer DPTR. While instructions in the C51 Architecture always use DPTR as the data pointer, instructions in the C251 Architecture can use any word or dword register as a data pointer.

DPXL, the byte in location 57 , specifies the region of memory ( $00:-\mathrm{FF}$ :) that maps into the $64-$ Kbyte external data memory space in the C51 Architecture. In other words, the MOVX instruction addresses the region specified by DPXL when it moves data to and from external memory. The reset value of DPXL is 01 h .

### 3.4.2.3. Extended Stack Pointer, SPX

Dword register DR60 is the stack pointer, SPX (See Figure 3.7. ). The byte at (location 63) is the 8 -bit stack pointer, SP, in the C51 Architecture. The byte at location 62 is the stack pointer high, SPH. The two bytes allow the stack to extend to the top of memory region 00:. SP and SPH can be accessed as SFRs.
Two instructions, PUSH and POP directly address the stack pointer. Subroutine calls (ACALL, ECALL, LCALL) and returns (ERET, RET, RETI) also use the stack pointer. To preserve the stack, do not use DR60 as a general-purpose register.

Figure 3.7. Dedicated Registers in the Register File and their Corresponding SFRs

### 3.5. Special Function Registers (SFRs)

The Special Function Registers (SFRs) reside in their associated on-chip peripherals or in the core. SFR addresses are preceded by "S:" to differentiate them from addresses in the memory space. Unoccupied locations in the SFR space are unimplemented, i.e., no register exists. If an unimplemented SFR location is read, it returns an unspecified value.

## Note :

SFRs may be accessed only as bytes; they may not be accessed as words or dwords.

Table 3.4. Core SFRs

| Mnemonic | Name | Address |
| :--- | :--- | :---: |
| A $^{\star}$ | Accumulator | S:E0h |
| B $^{\star}$ | B register | S:F0h |
| PW | Program Status Word | S:D0h |
| PSW1 | Program Status Word 1 | S:D1h |
| SP | Stack Pointer - LSB of SPX | S:81h |
| SPH $^{\star}$ | Stack Pointer high - MSB of SPX | S:BEh |
| DPTR $^{\star}$ | Data Pointer (2 bytes) | - |
| DPL $^{\star}$ | Low Byte of DPTR | S:82h |
| DPH ${ }^{\star}$ | high Byte of DPTR | S:83h |
| DPXL |  |  |
| IE0 | Data Pointer, Extended Low | S:84h |
| IE1 | Interrupt Enable Control 0 | S:A8h |
| IPL0 | Interrupt Enable Control 1 | S:B1h |
| IPL1 | Interrupt Priority Control Low 0 | S:B3h |
| IPH0 | Interrupt Priority Control Low 1 | S:B7h |
| IPH1 | Interrupt Priority Control High 0 | S:B2h |

## Note:

* These SFRs can also be accessed by their corresponding registers in the register file (See Table 3.3.

## Programming

The instruction set for the C251 Architecture is a superset of the instruction set for the C51 Architecture. This chapter describes the addressing modes and summarizes the instruction set, which is divided into data instructions, bit instructions, and control instructions. (Chapter 5, "Instruction Set Reference" contains an opcode map and the detailed description of each instruction.)

## Notes:

- The instruction execution times given in Chapter 5 are for code executing from on-chip code memory and for data that is read from and written to on-chip RAM. Execution times are increased by executing code from external memory, accessing peripheral SFRs, accessing data in external memory, using a wait state, or extending the ALE pulse.
- For some instructions, accessing the port SFRs, $\mathrm{Px}(\mathrm{x}=0,1,2,3)$ increases the execution time. These cases are noted individually in the tables in Chapter 5.

### 4.1. Source Mode or Binary Mode Opcodes

Source mode and Binary mode refer to the two ways of assigning opcodes to the instruction set of the C251 Architecture. Depending on the application, one mode or the other may produce more efficient code. The mode is established during device reset based on the value of the SRC bit in configuration byte CONFIG0. For information regarding the configuration bytes, see the Product Design Guide.

Binary mode and source mode refer to two ways of assigning opcodes to the instruction set for the C251 Architecture. One of these modes must be selected when the chip is configured. Depending on the application, binary mode or source mode may produce more efficient code. This section describes the binary and source modes and provides some guidelines for selecting the mode for your application.

The C251 Architecture has two types of instructions:

- Instructions that originate in the C51 Architecture
- Instructions that are unique to the C251 Architecture

Figure 4.1. shows the opcode map for the binary mode. Area I and area II make up the opcode map for the instructions that are unique to the C251 Architecture. Note that some of these opcodes are reserved for future instructions. The opcode values for areas II and III are identical ( $06 \mathrm{H}-\mathrm{FFH}$ ). To distinguish between the two areas in binary mode, the opcodes in area III are given the prefix A5H (the A5H instruction is not implemented in the native C51 Architecture). The area III opcodes are thus A506H-A5FFH.

Figure 4.2. shows the opcode map for source mode. Areas II and III have switched places (compare with Figure 4.1. ). In source mode, opcodes for instructions in area II require the A5F escape prefix while opcodes for instructions in area III (C251 Architecture) do not.

To illustrate the difference between the binary-mode and source-mode opcodes, Table 4.1. shows the opcode assignments for three sample instructions.

Table 4.1. Examples of Opcodes in Binary and Source Modes

| Instruction | Opcode |  |
| :--- | :--- | :--- |
|  | Binary Mode | Source Mode |
| DEC A | 14 H | 14 CH |
| SUBB A, R4 | 9 CH | A59CH |
| SUB R4, R4 | A59CH | 9 CH |

### 4.1.1. Selecting Binary Mode or Source Mode

If you have code that was written for a C51 microcontroller and you want to run it unmodified on a C251 microcontroller, choose binary mode. You can use the object code without reassembling the source code. You can also assemble the source code with an assembler for the C251 Architecture and have it produce object code that is binary-compatible with C51 microcontrollers. The remainder of this section discusses the selection of binary mode or source mode for code that may contain instructions from both architectures.

An instruction with a prefixed opcode requires one more byte for code storage, and if an additional fetch is required for the extra byte, the execution time is increased by one state. This means that using fewer prefixed opcodes produces more efficient code.
If a program uses only instructions from the C51 Architecture, the binary-mode code is more efficient because it uses no prefixes. On the other hand, if a program uses many more new instructions than instructions from the C51 Architecture, source mode is likely to produce more efficient code. For a program where the choice is not clear, the better mode can be found by experimenting with a simulator.

Figure 4.1. Binary Mode Opcode Map

Figure 4.2. Source Mode Opcode Map

### 4.2. Programming Features of the C251 Architecture

The instruction set for TSC80251 microcontrollers provides the user with new instructions that exploit the features of the C251 Architecture while maintaining compatibility with the instruction set for 80C51 microcontrollers. Many of the new instructions can operate on either 8-bit (byte), 16-bit (word) or 32-bit (dword) operands (In comparison with 8 -bit and 16 -bit operands, 32 -bit operands are accessed with fewer addressing modes.). This capability increases the ease and efficiency of programming TSC80251 microcontrollers in a high-level language such as C.
The instruction set is divided into "Data Instructions", "Bit Instructions" and "Control Instructions". Data instructions process 8 -bit, 16 -bit and 32 -bit data; bit instructions manipulate bits; and control instructions manage program flow.

### 4.2.1. Data Types

Table 4.2. lists the data types that are addressed by the instruction set. Words or dwords (double words) can be stored in memory starting at any byte address; alignment on two-byte or four-byte boundaries is not required. Words and dwords are stored in memory and the register file in big endian form.

Table 4.2. Data Types

| Data Type | Number of Bits |
| :--- | :---: |
| Bit | 1 |
| Byte | 8 |
| Word | 16 |
| Dword (Double Word) | 32 |

### 4.2.1.1. Order of Byte Storage for Words and Double Words

TSC80251 microcontrollers store words (2 bytes) and double words (4 bytes) in memory and in the register file in big endian form. In memory storage, the most significant byte (MSB) of the word or double word is stored in the memory byte specified in the instruction; the remaining bytes are stored at higher addresses, with the least significant byte (LSB) at the highest address. Words and double words can be stored in memory starting at any byte address. In the register file, the MSB is stored in the lowest byte of the register specified in the instruction. The code fragment in Figure 4.3. illustrates the storage of words and double words in big endian form.

### 4.2.2. Register Notations

In register-addressing instructions, specific indices denote the registers that can be used in that instruction. For example, the instruction ADD A,Rn uses"Rn" to denote any one of R0, R1, .., R7; i.e., the range of n is $0-7$. The instruction ADD Rm,\#data uses "Rm" to denote R0, R1, ..., R15; i.e., the range of m is $0-15$. Table 4.3. summarizes the notation used for the register indices. When an instruction contains two registers of the same type (e.g., MOV Rmd,Rms) the first index "d" denotes "destination" and the second index " $s$ " denotes "source".

### 4.2.3. Address Notations

In the C251 Architecture, memory addresses include a region number ( $00:, 01:, \ldots, \mathrm{FF}$ :). SFR addresses have a prefix "S:" (S:000h-S:1FFh). The distinction between memory addresses and SFR addresses is necessary, because memory locations 00:0000h-00:01FFh and SFR locations S:000h-S:1FFh can both be directly addressed in an instruction.

Contents of register file and memory after execution: $\begin{array}{ll}\text { MOV WR0, \#A3B6h } \\ & \text { MOV 00:0201h, WR0 } \\ & \text { MOV DR4 }\end{array}$
MOV DR4, \#0000C4D7h
Figure 4.3. Word and Double-word Storage in Big Endian Form

Table 4.3. Notation for Byte Registers, Word Registers, and Dword Registers

| Register Type | Register <br> Symbol | Destination <br> Register | Source <br> Register | Register Range |
| :---: | :---: | :---: | :---: | :--- |
|  | Ri | - | - | R0, R1 |
|  | Rn | - | - | R0-R7 |
|  | Rm | Rmd | Rms | R0-R15 |
| Word | WRj | WRjd | WRjs | WR0, WR2, WR4, ..., WR30 |
| Dword | DRk | DRkd | DRks | DR0, DR4, DR8, .., DR28,DR56, DR60 |

Instructions in the C51 Architecture use 80h-FFh as addresses for both memory locations and SFRs, because memory locations are addressed only indirectly and SFR locations are addressed only directly. For compatibility, software tools for TSC80251 controllers recognize this notation for instructions in the C51 Architecture. No change is necessary in any code written for 80C51 microcontrollers.
For new instructions in the C251 Architecture, the memory region prefixes ( $00:, 01:, \ldots, \mathrm{FF}$ :) and the SFR prefix (S:) are required. Also, software tools for the C251 Architecture permit 00: to be used for memory addresses $00 \mathrm{~h}-\mathrm{FFh}$ and permit the prefix S: to be used for SFR addresses in instructions in the C51 Architecture.

### 4.2.4. Addressing Modes

The C251 Architecture supports the following addressing modes:

- Register addressing

The instruction specifies the register that contains the operand.

- Immediate addressing

The instruction contains the operand.

- Direct addressing

The instruction contains the operand address.

- Indirect addressing

The instruction specifies the register that contains the operand address.

- Displacement addressing

The instruction specifies a register and an offset. The operand address is the sum of the register contents (the base address) and the offset.

- Relative addressing

The instruction contains the signed offset from the next instruction to the target address (the address for transfer of control, e.g., the jump address).

- Bit addressing

The instruction contains the bit address.

### 4.3. Program Status Words

The Program Status Word (PSW) register and the Program Status Word 1 (PSW1) register contain four types of bits (See Figure 4.7. and Figure 4.8. ):

- CY, AC, OV, N and Z are flags set by hardware to indicate the result of an operation.
- The P bit indicates the parity of the accumulator.
- Bits RS0 and RS1 are programmed by software to select the active register bank for registers R0-R7.
- F0 and UD are available to the user as general-purpose flags.

The PSW and PSW1 registers are read/write registers; however, the parity bit in the PSW is not affected by a write. Individual bits can be addressed with the bit instructions ("Bit Instructions"). The PSW and PSW1 bits are used implicitly in the conditional jump instructions ("Conditional Jumps").

The PSW register is identical to the PSW register in 80C51 microcontrollers. The PSW1 register exists only in TSC80251 microcontrollers. Bits CY, AC, RS0, RS1, and OV in PSW1 are identical to the corresponding bits in PSW, i.e., the same bit can be accessed in either register. Table 4.4. lists the instructions that affect the CY, AC, OV, N and Z bits.

Table 4.4. The Efffects of Instructions on the PSW and PSW1 Flags

| Instruction Type | Instruction | Flags Affected ${ }^{(1)}$ |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | CY | OV | $\mathrm{AC}^{(2)}$ | N | Z |
| Arithmetic | ADD, ADDC, SUB, CMP | X | X | X | X | X |
|  | INC, DEC |  |  |  | X | X |
|  | MUL, DIV ${ }^{(3)}$ | 0 | X |  | X | X |
|  | DA | X |  |  | X | X |
| Logical | ANL, ORL, XRL, CLR A, CPL A, RL, RR, SWAP |  |  |  | X | X |
|  | RLC, RRC, SRL, SLL, SRA ${ }^{(4)}$ | X |  |  | X | X |
| Program Control | CJNE | X |  |  | X | X |
|  | DJNE |  |  |  | X | X |

Notes :

1. $X=$ the flag can be affected by the instruction. $0=$ the flag is cleared by the instruction.
2. The AC flag is affected only by operations on 8-bit operands.
3. If the divisor is zero, the OV flag is set, and the other bits are meaningless.
4. For SRL, SLL and SRA instructions, the last bit shifted out is stored in the CY bit.

### 4.4. Data Instructions

Data instructions consist of arithmetic, logical, and data-transfer instructions for 8-bit, 16-bit and 32-bit data. This section describes the data addressing modes and the set of data instructions.

### 4.4.1. Data Addressing Modes

This section describes the data addressing modes, which are summarized in two tables: Table 4.6. for the instructions that are native to the C51 Architecture and Table 4.6. for the data instructions unique to the C251 Architecture.

## Notes:

- References to registers R0-R7, WR0-WR6, DR0 and DR4 always refer to the register bank that is currently selected by the PSW and PSW1 registers. Registers in all banks (active and inactive) can be accessed as memory locations in the range $00 \mathrm{~h}-1 \mathrm{Fh}$.
- Instructions from the C51 Architecture access external memory through the region of memory specified by byte DPXL in the extended data pointer register, DPX (DR56). Following reset, DPXL contains 01h, which maps the external memory to region 01 :. You can specify a different region by writing to DR56 or the DPXL SFR.

### 4.4.1.1. Addressable Registers

Both Architectures address registers directly.

- C251 Architecture In the register addressing mode, the operand(s) in a data instruction are in byte registers (R0-R15), word registers (WR0, WR2, ..., WR30) or dword registers (DR0, DR4, ..., DR28, DR56, DR60).
- C51 Architecture

Instructions address registers R0-R7 only.

### 4.4.1.2. Immediate Addressing

- C251 Architecture

In the immediate addressing mode, the instruction contains the data operand itself. Byte operations use 8-bit immediate data (\#data); word operations use 16-bit immediate data (\#data16). Dword operations use 16-bit immediate data in the lower word and either zeros in the upper word (denoted by \#0data16) or ones in the upper word (denoted by \#1data16). MOV instructions that place 16-bit immediate data into a dword register (DRk), place the data either into the upper word while leaving the lower word unchanged, or into the lower word with a sign extension or a zero extension.
The increment and decrement instructions contain immediate data (\#short $=1,2$, or 4 ), which specifies the amount of the increment/decrement.

- C51 Architecture

Instructions use only 8 -bit immediate data (\#data).

### 4.4.1.3. Direct Addressing

- C251 Architecture

In the direct addressing mode, the instruction contains the address of the data operand. The 8 -bit direct mode addresses on-chip RAM (dir8 $=00: 0000 \mathrm{~h}-00: 007 \mathrm{Fh}$ ) as both bytes and words, and addresses the SFRs (dir8 = S:080h-S:1FFh) as bytes only. The 16-bit direct mode addresses both bytes and words in memory (dir16 = 00:0000h-00:FFFFh).

- C51 Architecture

The 8 -bit direct mode addresses 256 bytes of on-chip RAM (dir8 $=00 \mathrm{~h}-7 \mathrm{Fh}$ ) as bytes only and the SFRs (dir8 $=$ $80 \mathrm{~h}-\mathrm{FFh}$ ) as bytes only.

Table 4.5. Addressing Modes for Data Instruction in the C51 Architecture

| Mode | Address Range of Operand | Assembly <br> Language <br> Reference | Comments |
| :---: | :---: | :---: | :---: |
| Register | 00h-1Fh | R0-R7 (Bank selected by PSW) |  |
| Immediate | Operand in Instruction | \#data = \#00h-\#FFh |  |
| Direct | 00h-7Fh | dir8 $=00 \mathrm{~h}-7 \mathrm{Fh}$ | On-chip RAM |
|  | SFRs | $\text { dir8 }=80 \mathrm{~h}-\mathrm{FFh}$ <br> or SFR mnemonic | SFR address |
| Indirect | 00h-FFh | @R0, @R1 | Accesses on-chip RAM or the lowest 256 bytes of external data memory (MOVX) |
|  | 0000h-FFFFh | $\begin{aligned} & \text { @ DPTR, } \\ & \text { @ A+DPTR } \end{aligned}$ | Accesses external data memory (MOVX) |
|  | 0000h-FFFFh | $\begin{aligned} & \text { @ A+DPTR, } \\ & \text { @ A+PC } \end{aligned}$ | Accesses region FF : of code memory (MOVC) |

### 4.4.1.4. Indirect Addressing

In arithmetic and logical instructions that use indirect addressing, the source operand is always a byte, and the destination is either the accumulator or a byte register (R0-R15). The source address is a byte, word or dword. The two architectures do indirect addressing via different registers:

- C251 Architecture

Memory is indirectly addressed via word and dword registers :

- Word register (@WRj, j=0, 2, 4, ..., 30)

The 16-bit address in WRj can access locations 00:0000h-00:FFFFh.

- Dword register (@DRk, k=0,4, 8, ... 28, 56, and 60)

The 24 least significant bits can access the entire 16-Mbyte address space. The upper eight bits of DRk must be 0 . (If you use DR60 as a general data pointer, be aware that DR60 is the extended stack pointer register SPX.)

- C51 Architecture

Instructions use indirect addressing to access on-chip RAM, code memory, and external data RAM.

- Byte register (@Ri, i=0,1)

Registers R0 and R1 indirectly address on-chip memory locations 00h-FFh and the lowest 256 bytes of external data RAM.

- 16-bit data pointer (@DPTR or @A+DPTR)

The MOVC and MOVX instructions use these indirect modes to access code memory and external data RAM.

- 16-bit program counter (@A+PC)

The MOVC instruction uses this indirect mode to access code memory.

Table 4.6. Addressing Modes for Data Instruction in the C251 Architecture

| Mode | Address Range of Operand | Assembly Language Reference | Comments |
| :---: | :---: | :---: | :---: |
| Register | 00:0000h-00:001Fh | R0-R15, WR0-WR30, DR0-DR28, DR56, DR60 | R0-R7, WR0-WR6, and DR4 are in the register bank currently selected by the PSW and PSW1 |
| Immediate 2 bits | N.A. (Operand is in the instruction) | \#short $=1,2$, or 4 | Used only in increment and decrement instructions |
| Immediate 8 bits | N.A. (Operand is in the instruction) | \#data8 = \#00h-\#FFh |  |
| Immediate 16 bits | N.A. (Operand is in the instruction) | \#data16 = \#0000h-\#FFFFh |  |
| Direct, 8 address bits | 00:0000h-00:007Fh | dir8 = 00:0000h-00:007Fh | On-chip RAM |
|  | SFRs | dir8 = S:080h-S:1FFh (2) <br> or SFR mnemonic | SFR address |
| Direct, 16 address bits | 00:0000h-00:FFFFh | dir16 = 00:0000h-00:FFFFh |  |
| Indirect, 16 address bits | 00:0000h-00:FFFFh | @WR0-@WR30 |  |
| Indirect, 24 address bits | 00:0000h-FF:FFFFh | @DR0-@DR30, @DR56, <br> @DR60 | Upper 8 bits of DRk must be 00h |
| Displacement, 16 address bits | 00:0000h-00:FFFFh | @WRj +dis16 = @WR0 +0h through @WR30 +FFFFh | Offset is signed; address wraps around in region 00: |
| Displacement, 24 address bits | 00:0000h-FF:FFFFh | $\begin{aligned} & \text { @DRk + dis24 = } \\ & \text { @DR0 +0h through @DR28 } \\ & \text { +FFFFh, } \\ & \text { @DR56 +(0h-FFFFh), } \\ & \text { @DR60 +(0h-FFFFh) } \end{aligned}$ | Offset is signed, upper 8 bits of DRk must 00h |

## Notes:

1. These registers are accessible in the memory space as well as in the register file.
2. The C251 Architecture supports SFRs in locations S:000h-S:1FFh.

### 4.4.1.5. Displacement Addressing

Several move instructions use displacement addressing to move bytes or words from a source to a destination. Sixteen-bit displacement addressing (@WRj+dis16) accesses indirectly the lowest 64 Kbytes in memory. The base address can be in any word register WRj. The instruction contains a 16 -bit signed offset which is added to the base address. Only the lowest 16 bits of the sum are used to compute the operand address. If the sum of the base address and a positive offset exceeds FFFFh, the computed address wraps around within region 00: (e.g. F000h +2005 h becomes 1005h). Similarly, if the sum of the base address and a negative offset is less than zero, the computed address wraps around the top of region 00: (e.g., 2005h + F000h becomes 1005h).
24-bit displacement addressing (@DRk+dis24) accesses indirectly the entire 16-Mbyte address space. The base address must be in DR0, DR4, ... DR24, DR28, DR56, or DR60. The upper byte in the dword register must be zero. The instruction contains a 16-bit signed offset which is added to the base address.

### 4.4.2. Arithmetic Instructions

The set of arithmetic instructions is greatly expanded in the C251 Architecture. The ADD and SUB instructions (See Table 5.19) operate on byte and word data that is accessed in several ways :

- as the contents of the accumulator, a byte register (Rn), or a word register (WRj)
- in the instruction itself (immediate data)
- in memory via direct or indirect addressing

The ADDC and SUBB instructions are the same as those for 80C51 microcontrollers.
The CMP (compare) instruction (See Table 5.20) calculates the difference of two bytes or words and then writes to flags CY, OV, AC, N, and Z in the PSW and PSW1 registers. The difference is not stored. The operands can be addressed in a variety of modes. The most frequent use of CMP is to compare data or addresses preceding a conditional jump instruction.

Table 5.21 lists the INC (increment) and DEC (decrement) instructions. The instructions for 80C51 microcontrollers are supplemented by instructions that can address byte, word, and dword registers and increment or decrement them by 1,2 , or 4 (denoted by \#short). These instructions are supplied primarily for register-based address pointers and loop counters.
The C251 Architecture provides the MUL (multiply) and DIV (divide) instructions for unsigned 8-bit and 16-bit data (Table 5.22). Signed multiply and divide are left for the user to manage through a conversion process. The following operations are implemented :

- eight-bit multiplication: 8 bits x 8 bits $\rightarrow 16$ bits
- sixteen-bit multiplication: 16 bits x 16 bits $\rightarrow 32$ bits
- eight-bit division: 8 bits $/ 8$ bits $\rightarrow 16$ bits ( 8 -bit quotient, 8 -bit remainder)
- sixteen-bit division: 16 bits / 16 bits $\rightarrow 32$ bits (16-bit quotient, 16 -bit remainder)

These instructions operate on pairs of byte registers (Rmd,Rms), word registers (WRjd,WRjs), or the accumulator and B register (A, B). For 8-bit register multiplies, the result is stored in the word register that contains the first operand register. For example, the product from an instruction MUL R3,R8 is stored in WR2. Similarly, for 16-bit multiplies, the result is stored in the dword register that contains the first operand register. For example, the product from the instruction MUL WR6,WR18 is stored in DR4.
For 8-bit divides, the operands are byte registers. The result is stored in the word register that contains the first operand register. The quotient is stored in the lower byte, and the remainder is stored in the higher byte. A 16-bit divide is similar. The first operand is a word register, and the result is stored in the double word register that contains that word register. If the second operand (the divisor) is zero, the overflow flag (OV) is set and the other bits in PSW and PSW1 are meaningless.

### 4.4.3. Logical Instructions

The C251 Architecture provides a set of instructions that perform logical operations. The ANL, ORL, and XRL (logical AND, logical OR, and logical exclusive OR) instructions operate on bytes and words that are accessed via several addressing modes (See Table 5.23). A byte register, word register, or the accumulator can be logically combined with a register, im-mediate data, or data that is addressed directly or indirectly. These instructions affect the Z and N flags.
In addition to the CLR (clear), CPL (complement), SWAP (swap), and four rotate instructions that operate on the accumulator, TSC80251 microcontrollers have three shift commands for byte and word registers :

- SLL (Shift Left Logical) shifts the register one bit left and replaces the LSB with 0 .
- SRL (Shift Right Logical) shifts the register one bit right and replaces the MSB with 0 .
- SRA (Shift Right Arithmetic) shifts the register one bit right; the MSB is unchanged.

### 4.4.4. Data Transfer Instructions

Data transfer instructions copy data from one register or memory location to another. These instructions include the move instructions (See Table 5.24) and the exchange, PUSH, and pop instructions (See Table 5.24). Instructions that move only a single bit are listed with the other bit instructions in Table 5.26.
MOV (Move) is the most versatile instruction, and its addressing modes are expanded in the C251 Architecture. MOV can transfer a byte, word or dword between any two registers or between a register and any location in the address space.
The MOVX (Move External) instruction moves a byte from external memory to the accumulator or from the accumulator to memory. The external memory is in the region specified by DPXL, whose reset value is 01 h .

The MOVC (Move Code) instruction moves a byte from code memory (region FF:) to the accumulator.
MOVS (Move with Sign Extension) and MOVZ (Move with Zero Extension) move the contents of an 8-bit register to the lower byte of a 16-bit register. The upper byte is filled with the sign bit (MOVS) or zeros (MOVZ). The MOVH (Move to high Word) instruction places 16-bit immediate data into the high word of a dword register.
The XCH (Exchange) instruction interchanges the contents of the accumulator with a register or memory location. The XCHD (Exchange Digit) instruction interchanges the lower nibble of the accumulator with the lower nibble of a byte in on-chip RAM. XCHD is useful for BCD (binary coded decimal) operations.
The PUSH and POP instructions facilitate storing information (PUSH) and then retrieving it (POP) in reverse order. PUSH can push a byte, a word or a dword onto the stack, using the immediate, direct or register addressing modes. POP can pop a byte or a word from the stack to a register or to memory.

### 4.5. Bit Instructions

A bit instruction addresses a specific bit in a memory location or SFR. There are four categories of bit instructions:

- SETB (Set Bit), CLR (Clear Bit), CPL (Complement Bit). These instructions can set, clear or complement any addressable bit.
- ANL (And Logical), ANL/ (And Logical Complement), ORL (OR Logical), ORL/ (Or Logical Complement). These instructions allow anding and oring of any addressable bit or its complement with the CY flag.
- MOV (Move) instructions transfer any addressable bit to the carry (CY) bit or vice versa.
- Bit-conditional jump instructions execute a jump if the bit has a specified state. The bit-conditional jump instructions are classified with the control instructions.

### 4.5.1. Bit Addressing

The bits that can be individually addressed are in the on-chip RAM and the SFRs (See Table 4.7. ). The bit instructions that are unique to the C251 Architecture can address a wider range of bits than the instructions from the C51 Architecture.

There are some differences in the way the instructions from the two Architectures address bits. In the C51 Architecture, a bit (denoted by bit51) can be specified in terms of its location within a certain register, or it can be specified by a bit address in the range 00h-7Fh. The C251 Architecture does not have bit addresses as such. A bit can be addressed by name or by its location within a certain register, but not by a bit address.
Table 4.8. illustrates bit addressing in the two Architectures by using two sample bits:

- RAMBIT is bit 5 in RAMREG, which is location 23h. ("RAMBIT" and "RAMREG" are assumed to be defined in user code.)
- IT1 is bit 2 in TCON, which is an SFR at location 88h.

Table 4.7. Bit-addressable Locations

| Architecture | Bit-addressable Locations |  |
| :--- | :---: | :--- |
|  | On-chip RAM | SFRs |
| C251 Architecture | $20 \mathrm{~h}-7 \mathrm{Fh}$ | All defined SFRs |
| C51 Architecture | $20 \mathrm{~h}-2 \mathrm{Fh}$ | SFRs with addresses ending in 0 h or $8 \mathrm{~h}: 80 \mathrm{~h}, 88 \mathrm{~h}, 90 \mathrm{~h}, 98 \mathrm{~h}, \ldots, \mathrm{~F} 8 \mathrm{~h}$ |

Table 4.9. lists the addressing modes for bit insructions, and Table 5.26 summarizes the bit instructions. "bit" denotes a bit that is addressed by a new instruction in the C251 Architecture, and "bit51" denotes a bit that is addressed by an instruction in the C51 Architecture.

Table 4.8. Two Samples of Bits Addressing

| Location | Addressing Mode | C51 Architecture | C251 Architecture |
| :--- | :--- | :--- | :--- |
| On-chip RAM | Register Name | RAMREG.5 | RAMREG.5 |
|  | Register Address | 23 h .5 | 23 h .5 |
|  | Bit Name | RAMBIT | RAMBIT |
|  | Bit Address | 1Dh | NA |
| SFR | Register Name | TCON.2 | TCON.2 |
|  | Register Address | 88.2 h | S:88.2h |
|  | Bit Name | IT1 | IT1 |
|  | Bit Address | 8 A | NA |

Table 4.9. Addressing Modes for Bit Instructions

| Architecture | Variants | Bit Address | Memory/SFR Address | Comments |
| :--- | :--- | :--- | :--- | :--- |
| C251 (bit) | Memory | NA | $20 \mathrm{~h} .0-7 \mathrm{Fh} .7$ |  |
|  | SFR | NA | All defined SFRs |  |
|  | Memory | $00 \mathrm{~h}-7 \mathrm{Fh}$ | $20 \mathrm{~h} .0-7 \mathrm{Fh} .7$ |  |
|  | SFR | $80 \mathrm{~h}-\mathrm{F} 8 \mathrm{~h}$ | XXh.0-XXh.7, where XX $=$ <br> $80,88,90,98, \ldots, \mathrm{~F} 0, \mathrm{~F} 8$ | SFRs are not defined at all <br> bit-addressable locations |

### 4.6. Control Instructions

Control instructions "instructions that change program flow" include calls, returns, and conditional and unconditional jumps (See Table 5.27). Instead of executing the next instruction in the queue, the processor executes a target instruction. The control instruction provides the address of a target instruction either implicitly, as in a return from a subroutine, or explicitly, in the form of a relative, direct, or indirect address.

TSC80251 microcontrollers have a 24-bit program counter (PC), which allows a target instruction to be anywhere in the 16-Mbyte address space. however, as discussed in this section, some control instructions restrict the target address to the current $2-$ Kbyte or $64-$ Kbyte address range by allowing only the lowest 11 or lowest 16 bits of the program counter to change.

### 4.6.1. Addressing Modes for Control Instructions

Table 4.10. lists the addressing modes for the control instructions.

- Relative addressing:

The control instruction provides the target address as an 8-bit signed offset (rel) from the address of the next instruction.

- Direct addressing:

The control instruction provides a target address, which can have 11 bits (addr11), 16 bits (addr16), or 24 bits (addr24). The target address is written to the PC.

- addr11: Only the lower 11 bits of the PC are changed; i.e., the target address must be in the current 2-Kbyte block (the 2-Kbyte block that includes the first byte of the next instruction).
- addr16: Only the lower 16 bits of the PC are changed; i.e., the target address must be in the current 64-Kbyte region (the $64-$ Kbyte region that includes the first byte of the next instruction).
- addr24: The target address can be anywhere in the 16-Mbyte address space.
- Indirect addressing:

There are two types of indirect addressing for control instructions:

- For the instructions LCALL @WRj and LJMP @WRj, the target address is in the current 64-Kbyte region. The $16-$ bit address in WRj is placed in the lower 16 bits of the PC. The upper eight bits of the PC remain unchanged from the address of the next instruction.
- For the instruction JMP @A+DPTR, the sum of the accumulator and DPTR is placed in the lower 16 bits of the PC, and the upper eight bits of the PC are FF:, which restricts the target address to the code memory space of the C51 Architecture.

Table 4.10. Addressing Modes for Control Instructions

| Description | Address Bits <br> Provided | Address Range |
| :--- | :---: | :--- |
| Relative, 8-bit relative address (rel) | 8 | -128 to +127 from first byte of next instruction |
| Direct, 11-bit target address (addr11) | 11 | Current 2 Kbytes |
| Direct, 16-bit target address (addr16) | 16 | Current 64 Kbytes |
| Direct, 24-bit target address (addr24) <br> $\star$ | 24 | $00: 0000 \mathrm{~h}$-FF:FFFFh |
| Indirect (@WRj) $\star$ | 16 | Current 64 Kbytes |
| Indirect (@A +DPTR) | 16 | 64-Kbyte region specified by DPXL (reset value $=01 \mathrm{~h}$ ) |

Note:

* These modes are not used by instructions in the C51 Architecture.

### 4.6.2. Conditional Jumps

The C251 Architecture supports bit-conditional jumps, compare-conditional jumps, and jumps based on the value of the accumulator. A bit-conditional jump is based on the state of a bit. In a compare-conditional jump, the jump is based on a comparison of two operands. All conditional jumps are relative, and the target address (rel) must be in the current 256-byte block of code. The instruction set includes three kinds of bit-conditional jumps :

- JB (Jump on Bit): Jump if the bit is set.
- JNB (Jump on Not Bit): Jump if the bit is clear.
- JBC (Jump on Bit then Clear it): Jump if the bit is set; then clear it.

Compare-conditional jumps test a condition resulting from a compare (CMP) instruction that is assumed to precede the jump instruction. The jump instruction examines the PSW and PSW1 registers and interprets their flags as though they were set or cleared by a compare (CMP) instruction. Actually, the state of each flag is determined by the last instruction that could have affected that flag.
The condition flags are used to test one of the following six relations between the operands :

- equal $(=)$, not equal $(\neq)$
- greater than (>), less than (<)
- greater than or equal $(\geq)$, less than or equal $(\leq)$

For each relation there are two instructions, one for signed operands and one for unsigned operands (See Table 4.11.).

Table 4.11. Compare-conditional Jump Instructions

| Operand Type | Relation |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | = | $\neq$ | > | $<$ | $\geq$ | $\leq$ |
| Unsigned | JE | JNE | JG | JL | JGE | JLE |
| Signed |  |  | JSG | JSL | JSGE | JSLE |

### 4.6.3. Unconditional Jumps

There are five unconditional jumps. NOP and SJMP jump to addresses relative to the program counter. AJMP, LJMP, and EJMP jump to direct or indirect addresses.

- NOP (No Operation) is an unconditional jump to the next instruction.
- SJMP (Short Jump) jumps to any instruction within -128 to 127 of the next instruction.
- AJMP (Absolute Jump) changes the lowest 11 bits of the PC to jump anywhere within the current 2-Kbyte block of memory. The address can be direct or indirect.
- LJMP (Long Jump) changes the lowest 16 bits of the PC to jump anywhere within the current 64-Kbyte region.
- EJMP (Extended Jump) changes all 24 bits of the PC to jump anywhere in the 16-Mbyte address space. The address can be direct or indirect.

### 4.6.4. Calls and Returns

The C251 Architecture provides relative, direct, and indirect calls and returns.

- ACALL (Absolute Call) pushes the lower 16 bits of the next instruction address onto the stack and then changes the lower 11 bits of the PC to the 11-bit address specified by the instruction. The call is to an address that is in the same 2-Kbyte block of memory as the address of the next instruction.
- LCALL (Long Call) pushes the lower 16 bits of the next-instruction address onto the stack and then changes the lower 16 bits of the PC to the 16 -bit address specified by the instruction. The call is to an address in the same 64-Kbyte block of memory as the address of the next instruction.
- ECALL (Extended Call) pushes the 24 bits of the next instruction address onto the stack and then changes the 24 bits of the PC to the 24-bit address specified by the instruction. The call is to an address anywhere in the 16-Mbyte memory space.
- RET (Return) pops the top two bytes from the stack to return to the instruction following a subroutine call. The return address must be in the same 64-Kbyte region.
- ERET (Extended Return) pops the top three bytes from the stack to return to the address following a subroutine call. The return address can be anywhere in the 16-Mbyte address space.
- RETI (Return from Interrupt) provides a return from an interrupt service routine. The operation of RETI depends on the INTR bit in the CONFIG1 configuration byte (See Product Design Guide):
- For $\operatorname{INTR}=0$, an interrupt pushes the two lower bytes of the PC onto the stack in the following order : PC.7:0, PC.15:8. The RETI instruction pops these two bytes and uses them as the 16 -bit return address in region FF:. RETI also restores the interrupt logic to accept additional interrupts at the same priority level as the one just processed.
- For INTR = 1, an interrupt pushes the three PC bytes and PSW1 onto the stack in the following order: PSW1, PC.23:16, PC.7:0, PC.15:8. The RETI instruction pops these four bytes and then returns to the specified 24-bit address, which can be anywhere in the $16-$ Mbyte address space. RETI also clears the interrupt request line. (See the note in Table 4.10. regarding compatibility with code written for 80C51 microcontrollers.)
The TRAP instruction which caues an interrupt call is useful for the development of emulations of an TSC80251 microcontroller.

### 4.6.5. Interrupt Processing

Interrupt processing is a dynamic operation that begins when a source requests an interrupt and lasts until the execution of the first instruction in the interrupt service routine (See Figure 4.4. ). Response time is the amount of time between the interrupt request and the resulting break in the current instruction stream. Latency is the amount of time between the interrupt request and the execution of the first instruction in the interrupt service routine. These periods are dynamic due to the presence of both fixed-time sequences and several variable conditions. These conditions contribute to total elapsed time.

Figure 4.4. Interrupt Process

Both response time and latency begin with the request. The subsequent minimum fixed sequence comprises the interrupt sample, poly, and request operations. The variables consist of (but are not limited to): specific instructions in use at request time, internal versus external interrupt source requests, internal versus external program operation, stack location, presence of wait states, page-mode operation and branch pointer length.

## Note:

In the following discussion external interrupt request pins are assumed to be inactive for at least four state times prior to assertion. In this chapter all external hardware signals maintain some setup period (i.e., less than one state time). Signals must meet $V_{I H}$ and $V_{I L}$ specifications prior to any state time under discussion. This setup state time is not included in examples or calculations for either response or latency.

### 4.6.6. Minimum Fixed Interrupt Time

All interrupts are sampled or polled every four state times (See Figure 4.4. ). One additional state time is required for a context switch request. For code branches to jump locations in the current 64-Kbyte memory region (compatible with 80C51 microcontrollers), the context switch time is 11 states. Therefore, the minimum fixed poll and request time is 16 states ( 4 poll states +1 request state +11 states for the context switch $=16$ state times).

Therefore, this minimum fixed period rests upon four assumptions:

- The source request is an internal interrupt with high enough priority to take precedence over other potential interrupts.
- The request is coincident with internal execution and needs no instruction completion time.
- The program uses an internal stack location.
- The ISR is in on-chip OTPROM/ROM.

### 4.6.7. Variable Interrupt Parameters

Both response time and latency calculations contain fixed and variable components. By definition, it is often difficult to predict exact timing calculations for real-time requests. One large variable is the completion time of an instruction cycle coincident with the occurrence of an interrupt request. Worst-case predictions typically use the longest-executing instruction in an Architecture's code set. In the case of the TSC80251, the longest-executing instruction is a 16-bit divide (DIV). However, even this 21 -state instruction may have only 1 or 2 remaining states to complete before the interrupt system injects a context switch. This uncertainty affects both response time and latency.

### 4.6.7.1. Response Time Variables

Response time is defined as the start of a dynamic time period when a source requests an interrupt and lasts until a break in the current instruction execution stream occurs (See Figure 4.4. ). Response time (and therefore latency) is affected by two primary factors : the incidence of the request relative to the four-state-time sample window and the completion time of instructions in the response period (i.e., shorter instructions complete earlier than longer instructions).

## Note:

External interrupt signals require one additional state time in comparison to internal interrupts. This is necessary to sample and latch the pin value prior to a poll of interrupts. The sample occurs in the first half of the state time and the poll/request occurs in the second half of the next state time. Therefore, this sample and poll/request portion of the minimum fixed response and latency time is five states for internal interrupts and six states for external interrupts. External interrupts must remain active for at least five state times to guarantee interrupt recognition when the request occurs immediately after a sample has been taken (i.e., requested in the second half of a sample state time).

If the external interrupt goes active one state after the sample state, the pin is not resampled for another three states. After the second sample is taken and the interrupt request is recognized, the interrupt controller requests the context switch. The programmer must also consider the time to complete the instruction at the moment the context switch request is sent to the execution unit. If 9 states of a 10 -state instruction have completed when the context switch is requested, the total response time is 6 states, with a context switch immediately after the final state of the 10 -state instruction (See Figure 4.5. ).

Figure 4.5. Response Time Example

Conversely, if the external interrupt requests service in the state just prior to the next sample, response is much quicker. One state asserts the request, one state samples, and one state requests the context switch. If at that point the same instruction conditions exist, one additional state time is needed to complete the 10 -state instruction prior to the context switch (See Figure 4.6. ). The total response time in this case is four state times. The programmer must evaluate all pertinent conditions for accurate predictability.

Figure 4.6. Response Time Example

### 4.6.7.2. Computation of Worst Case Latency with Variables

Worst-case latency calculations assume that the longest TSC80251 instruction used in the program must fully execute prior to a context switch. The instruction execution time is reduced by one state with the assumption the instruction state overlaps the request state (therefore, 16-bit DIV is 21 states $-1=20$ states for latency calculations). The calculations add fixed and variable interrupt times (See Table 4.12. ) to this instruction time to predict latency. The worst-case latency (both fixed and variable times included) is expressed by a pseudo-formula :

## FIXED_TIME + VARIABLES + LONGEST_INSTRUCTION = MAXIMUM LATENCY PREDICTION

Table 4.12. Interrupt Latency Variables

| Variable | INT0\# <br> INT1\# <br> T2EX | External <br> Execution | Page <br> Mode | $>64$ <br> Jump to <br> ISR $^{(1)}$ | External <br> Memory <br> Wait <br> State | External <br> Stack <br> <64K | External <br> Stack <br> $>64 K$ | External <br> Stack <br> Wait <br> State |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Number of <br> States <br> Added | 1 | 2 | 1 | 8 | 1 per <br> bus cycle | 4 | 8 | 1 per <br> bus cycle |

## Notes:

1. < $64 \mathrm{~K} />64 \mathrm{~K}$ means inside/outside the 64 -Kbyte memory region where code is executing.
2. Base-case fixed time is 16 states and assumes :

- a 2-byte instruction is the first ISR byte
- Internal execution
- <64K jump to ISR
- Internal stack
- Internal peripheral interrupt

### 4.6.8. Latency Calculations

Assume the use of a zero-wait-state external memory where current instructions, the ISR and the stack are located within the same 64-Kbyte memory region (compatible with memory maps for 80C51 microcontrollers.) Further, assume there are 3 states yet to complete in the current 21 -state DIV instruction when INT0\# requests service. Also assume INT0\# has made the request one state prior to the sample state. Unlike in Figure 4.6., the response time for this assumption is three state times as the current instruction completes in time for the branch to occur. Latency calculations begin with the minimum fixed latency of 16 states. From Table 4.12., one state is added for an INT0\# request from external hardware; two states are added for external execution; and four states for an external stack in
 is 26 states. Worst-case latency calculations predict 43 states for this example due to inclusion of total DIV instruction time (less one state).

Table 4.13. Actual vs. Predicted Latency Calculations

| Latency Factors | Actual | Predicted |
| :--- | :---: | :---: |
| Base Case Minimum Fixed Time | 16 | 16 |
| INT0\# External Request | 1 | 1 |
| External Execution | 2 | 2 |
| <64K Byte Stack Location | 4 | 4 |
| Execution Time for Current (DIV instruction) | 3 | 20 |
| TOTAL | 26 | 43 |

### 4.6.9. Blocking Conditions

If all enable and priority requirements have been met, a single prioritized interrupt request at a time generates a vector cycle to an interrupt service routine. There are three causes of blocking conditions with hardware-generated vectors :

- An interrupt of equal or higher priority level is already in progress (defined as any point after the flag has been set and the RETI of the ISR has not executed).
- The current polling cycle is not the final cycle of the instruction in progress.
- The instruction in progress is RETI or any write to the IE0, IPH0 or IPL0 registers.

Any of these conditions blocks calls to interrupt service routines. Condition two ensures the instruction in progress completes before the system vectors to the ISR. Condition three ensures at least one more instruction executes before the system vectors to additional interrupts if the instruction in progress is a RETI or any write to IE0, IPH0 or IPL0. The complete polling cycle is repeated each four state times.

### 4.6.10. Interrupt Vector Cycle

When an interrupt vector cycle is initiated, the CPU breaks the instruction stream sequence, resolves all instruction pipeline decisions, and pushes multiple program counter (PC) bytes onto the stack. The CPU then reloads the PC with a start address for the appropriate ISR. The number of bytes pushed to the stack depends upon the INTR bit in the CONFIG1 configuration register (See Product Design Guide). The complete sample, poll, request and context switch vector sequence is illustrated in the interrupt latency timing diagram.

## Note:

If the interrupt flag for a level-triggered external interrupt is set but denied for one of the above conditions and is clear when the blocking condition is removed, then the denied interrupt is ignored. In other words, blocked interrupt requests are not buffered for retention.

### 4.6.11. ISRs in Process

ISR execution proceeds until the RETI instruction is encountered. The RETI instruction informs the processor the interrupt routine is completed. The RETI instruction in the ISR pops PC address bytes off the stack (as well as PSW1 for INTR = 1), and execution resumes at the suspended instruction stream.

## Note:

A simple RET instruction also returns execution to the interrupted program. In previous implementations this inappropriately allowed the system to operate as though an interrupt service routine is still in progress. The TSC80C251 allow use of both RETI and RET instructions for interrupt completion. However, for code expected to run properly on both 80C51 and TSC80C251 microcontrollers, only the execution of a RETI instruction is considered proper completion of the interrupt operation.
With the exception of TRAP, the start addresses of consecutive interrupt service routines are eight bytes apart. If consecutive interrupts are used (IE0 and TF0, for example, or TF0 and IE1), the first interrupt routine (if more than seven bytes long) must execute a jump to some other memory location. This prevents overlap of the start address of the following interrupt routine.

## PSW (S:D0h)

Program Status Word register

| CY | AC | FO | RS1 | RS0 | OV | UD | P |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{7}$ | $\mathbf{6}$ | $\mathbf{5}$ | $\mathbf{4}$ | $\mathbf{3}$ | $\mathbf{2}$ | $\mathbf{1}$ | $\mathbf{0}$ |

| Bit <br> Number | Bit <br> Mnemonic | Description |
| :---: | :---: | :---: |
| 7 | CY | Carry flag <br> The carry flag is set by an addition (ADD, ADDC) if there is a carry out of the MSB. It is set by a subtraction (SUB, SUBB) or compare (CMP) if a borrow is needed for the MSB. The carry flag is also affected by some rotate and shift instructions, logical bit instructions and bit move instructions, and the multiply (MUL) and decimal adjust (DA) instructions (See Table 4.4. ). |
| 6 | AC | Auxiliary Carry flag <br> The auxiliary flag is affected only by instructions that address 8 -bit operands. The AC flag is set if an arithmetic instruction with an 8-bit operand produces a carry out of bit 3 (from addition) or a borrow into bit 3 (from subtraction). Otherwise it is cleared. This flag is useful for BCD arithmetic (See Table 4.4.). |
| 5 | FO | Flag 0 <br> This general-purpose flag is available to the user. |
| 4 | RS1 | Register Bank Select bit 1 <br> This bit selects the memory locations that comprise the active bank of the register file (registers R0-R7). |
| 3 | RS0 | Register Bank Select bit 0 <br> This bit selects the memory locations that comprise the active bank of the register file (registers R0-R7). |
| 2 | OV | Overflow flag <br> This bit is set if an addition or subtraction of signed variables results in an overflow error (i.e., if the magnitude of the sum or differnecce is too great for the seven LSBs in 2's-complement representation). The overflow flag is also set if a multiplication product overflows one byte or if a division by zero is attempted. |
| 1 | UD | User-definable flag <br> This general-purpose flag is available to the user. |
| 0 | P | Parity bit <br> This bit indicates the parity of the accumulator. It is set if an odd number of bits in the accumulator are set. Otherwise, it is cleared. Not all instructions update the parity bit. |

Reset Value $=00000000 \mathrm{~b}$

## Instruction Set Reference

This chapter contains reference material for the instructions in the C251 Architecture. It includes an opcode map, a summary of the instructions-with instruction lengths and execution times-and a detailed description of each instruction. It contains the following tables:

- Table 5.1. through Table 5.4. describe the notation used for the instruction operands.
- Table 5.6. and Table 5.7. comprise the opcode map for the instruction set.
- Table 5.8. through Table 5.17. contain supporting material for the opcode map.
- Table 5.18. lists execution times for a group of instructions that access the Port SFRs.
- The following tables list the instructions with their lengths in bytes and their execution times:
- Add and Subtract Instructions, Table 5.7.
- Increment and Decrement Instructions, Table 5.8.
- Compare Instructions, Table 5.9.
- Logical Instructions, Table 5.10. to Table 5.11.
- Multiply, Divide and Decimal-adjust Instructions, Table 5.12.
- Move Instructions, Table 5.13. to Table 5.15.
- Bit Instructions, Table 5.16.
- Exchange, Push and Pop Instructions, Table 5.17.
- Control Instructions, Table 5.29.

## Notes:

The instruction execution times given in this appendix are for code executing from on-chip code memory and for data that is read from and written to on-chip RAM. Execution times are increased by executing code from external memory, accessing peripheral SFRs, accessing data in external memory, using a wait state, or extending the ALE pulse.

For some instructions, accessing the Port SFRs, Px, $x=0-3$, increases the execution time.

### 5.1. Instruction Set Summary

This section contains tables that summarize the instruction set. For each instruction there is a short description, its length in bytes, and its execution time in states (one state time is equal to two system clock cycles). There are two concurrent processes limiting the effective instruction throughput:

- Instruction Fetch
- Instruction Execution

Table 5.7. to Table 5.21. assume code executing from on-chip memory, then the CPU is fetching 16-bit at a time and this is never limiting the execution speed.
If the code is fetched from external memory, a pre-fetch queue will store instructions ahead of execution to optimize the memory bandwidth usage when slower instructions are executed. However, the effective speed may be limited depending on the average size of instructions (for the considered section of the program flow). The maximum average instruction throughput is provided by Table 5.1. depending on the external memory configuration (from Page Mode to Non-Page Mode and the maximum number of wait states). If the average size of instructions is not an integer, the maximum effective throughput is found by pondering the number of states for the neighbor integer values.

Table 5.1. Minimum Number of States per Instruction for given Average Sizes

| Average size <br> of <br> Instructions <br> (bytes) | Page Mode <br> (states) | Non-Page Mode (states) |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 0 Wait State | 1 Wait State | 2 Wait States | 3 Wait States | 4 Wait States |
| 1 |  | 2 | 3 | 4 | 5 | 6 |
| 2 |  | 4 | 6 | 8 | 10 | 12 |
| 3 |  | 6 | 9 | 12 | 15 | 18 |
| 4 | 4 | 8 | 12 | 16 | 20 | 24 |
| 5 | 5 | 10 | 15 | 20 | 25 | 30 |

If the average execution time of the considered instructions is larger than the number of states given by Table 5.1., this larger value will prevail as the limiting factor. Otherwise, the value from Table 5.1. must be taken. This is providing a fair estimation of the execution speed but only the actual code execution can provide the final value.

### 5.1.1. Notation for Instruction Operands

Table 5.2. to Table 5.6. provide Notation for Instruction Operands.
Table 5.2. Notation for Direct Addressing

| Direct Address | Description | C251 | C51 |
| :--- | :--- | :---: | :---: |
| dir8 | A direct 8-bit address. This can be a memory address (00h-7Fh) or a <br> SFR address (80h-FFh). It is a byte (default), word or double word <br> depending on the other operand. | r | r |
| dir16 | A 16-bit memory address (00:0000h-00:FFFFh) used in direct <br> addressing. | r |  |

Table 5.3. Notation for Immediate Addressing

| Immediate <br> Address | Description | C251 | C51 |
| :--- | :--- | :---: | :---: |
| \#data | An 8-bit constant that is immediately addressed in an instruction | r | r |
| \#data16 | A 16-bit constant that is immediately addressed in an instruction | r |  |
| \#0data16 <br> \#1data16 | A 32-bit constant that is immediately addressed in an instruction. The <br> upper word is filled with zeros (\#0data16) or ones (\#1data16). | ケ |  |
| \#short | A constant, equal to 1, 2, or 4, that is immediately addressed in an <br> instruction. | レ |  |

Table 5.4. Notation for Bit Addressing

| Direct Address | Description | C251 | C51 |
| :--- | :--- | :---: | :---: |
| bit51 | A directly addressed bit (bit number= 00h-FFh) in memory or an SFR. <br> Bits 00h-7Fh are the 128 bits in byte locations 20h-2Fh in the on-chip <br> RAM. Bits 80h-FFh are the 128 bits in the 16 SFRs with addresses that <br> end in 0h or 8h, S:80h, S:88h, S:90h,..., S:F0h, S:F8h. | r |  |
| bit | A directly addressed bit in memory locations 00:0020h-00:007Fh or in <br> any defined SFR. | r |  |

Table 5.5. Notation for Destination in Control Instructions

| Direct Address | Description | C251 | C51 |
| :---: | :---: | :---: | :---: |
| rel | A signed (two's complement) 8-bit relative address. The destination is -128 to +127 bytes relative to the next instruction's first byte. | $\checkmark$ | $\checkmark$ |
| addr11 | An 11-bit target address. The target is in the same 2-Kbyte block of memory as the next instruction's first byte. |  | $\gamma$ |
| addr16 | A 16-bit target address. The target can be anywhere within the same 64-Kbyte region as the next instruction's first byte. |  | $\checkmark$ |
| addr24 | A 24-bit target address. The target can be anywhere within the 16-Mbyte address space. | $\gamma$ |  |

Table 5.6. Notation for Register Operands

| Register | Description | C251 | C51 |
| :---: | :---: | :---: | :---: |
| @Ri | A memory location (00h-FFh) addressed indirectly via byte registers R0 or R1 |  | $\checkmark$ |
| $\begin{aligned} & \mathrm{Rn} \\ & \mathrm{n} \end{aligned}$ | Byte register R0-R7 of the currently selected register bank Byte register index: $\mathrm{n}=0-7$ |  | $\checkmark$ |
| Rm <br> Rmd <br> Rms <br> m, md, ms | Byte register R0-R15 of the currently selected register file Destination register <br> Source register <br> Byte register index: $\mathrm{m}, \mathrm{md}, \mathrm{ms}=0-15$ | $r$ |  |
| WRj <br> WRjd <br> WRjs <br> @WRj <br> @WRj + dis16 <br> $\mathrm{j}, \mathrm{jd}$, js | Word register WR0, WR2, ..., WR30 of the currently selected register file <br> Destination register <br> Source register <br> A memory location (00:0000h-00:FFFFh) addressed indirectly through word register WR0-WR30, is the target address for jump instructions. <br> A memory location (00:0000h-00:FFFFh) addressed indirectly through word register (WR0-WR30) + 16-bit signed (two's complement) displacement value <br> Word register index: j, jd, js= 0-30 | $r$ |  |
| DRk <br> DRkd <br> DRks <br> @DRk <br> @ DRk +dis16 <br> k, kd, ks | Dword register DR0, DR4, .., DR28, DR56, DR60 of the currently selected register file <br> Destination register <br> Source register <br> A memory location (00:0000h-FF:FFFFh) addressed indirectly through dword register DR0-DR28, DR56 and DR60, is the target address for jump instruction <br> A memory location (00:0000h-FF:FFFFh) addressed indirectly through dword register (DR0-DR28, DR56, DR60) + 16-bit (two's complement) signed displacement value <br> Dword register index: k , kd, ks $=0,4,8 \ldots, 28,56,60$ | $r$ |  |

## Notes:

1. A shaded cell denotes an instruction in the C51 Architecture.
2. If this instruction addresses an I/O Port (Px, x=0-3), add 1 to the number of states. Add 2 if it addresses a Peripheral SFR.
3. If this instruction addresses external memory location, add $N+2$ to the number of states ( $N$ : number of wait states).
4. If this instruction addresses external memory location, add $2(N+2)$ to the number of states ( $N$ : number of wait states).

Table 5.8. Summary of Increment and Decrement Instructions

| Mnemonic |  | Comments | Binar | Mode | Sourc | Mode |
|  |  |  | Bytes | States | Bytes | States |
| MOVH | DRk, \#data16 | 16-bit immediate data into upper word of dword register | 5 | 3 | 4 | 2 |
| MOVS | WRj, Rm | Byte register to word register with sign extension | 3 | 2 | 2 | 1 |
| MOVZ | WRj, Rm | Byte register to word register with zeros extension | 3 | 2 | 2 | 1 |
| MOVC | A, @ A + DPTR | Code byte relative to DPTR to ACC | 1 | $6^{(3)}$ | 1 | $6^{(3)}$ |
| C | A, @ A + PC | Code byte relative to PC to ACC | 1 | $6^{(3)}$ | 1 | $6^{(3)}$ |
|  | A, @Ri | Extended memory (8-bit address) to ACC ${ }^{(2)}$ | 1 | 4 | 1 | 5 |
| MOVX | A, @DPTR | Extended memory (16-bit address) to $\mathrm{ACC}^{(2)}$ | 1 | $3^{(4)}$ | 1 | $3^{(4)}$ |
| MOVX | @Ri, A | ACC to extended memory (8-bit address) ${ }^{(2)}$ | 1 | 4 | 1 | 4 |
|  | @ DPTR, A | ACC to extended memory (16-bit address) ${ }^{(2)}$ | 1 | $4^{(3)}$ | 1 | $4^{(3)}$ |

## Notes:

1. A shaded cell denotes an instruction in the C51 Architecture.
2. Extended memory addressed is in the region specified by DPXL (reset value $=01 \mathrm{~h})$.
3. If this instruction addresses external memory location, add $N+1$ to the number of states ( $N$ : number of wait states).
4. If this instruction addresses external memory location, add $N+2$ to the number of states ( $N$ : number of wait states).

|  | dir8, @Ri | Indirect address to direct address | 2 | $3^{(3)}$ | 3 | $4^{(3)}$ |
|  | dir8, \#data | Immediate data to direct address | 3 | $3^{(3)}$ | 3 | $3^{(3)}$ |
|  | @Ri, A | ACC to indirect address | 1 | 3 | 2 | 4 |
|  | @Ri, dir8 | Direct address to indirect address | 2 | $3^{(3)}$ | 3 | $4^{(3)}$ |
|  | @Ri, \#data | Immediate data to indirect address | 2 | 3 | 3 | 4 |
|  | DPTR, \#data 16 | Load Data Pointer with a 16-bit constant | 3 | 2 | 3 | 2 |

## Notes:

1. Instructions that move bits are in Table 5.16.
2. Move instructions from the C51 Architecture.
3. If this instruction addresses an I/O Port (Px, x=0-3), add 1 to the number of states. Add 2 if it addresses a Peripheral SFR.
4. Apply note 3 for each dir8 operand.

Table 5.15. Summary of Move Instructions (3/3)

| Move ${ }^{(1)}$ |  | V <dest>, <src> dest opnd $\leftarrow$ src opnd |  |  |  |  |

## Notes:

1. Instructions that move bits are in Table 5.16. .
2. Move instructions unique to the C251 Architecture.
3. If this instruction addresses an I/O Port (Px, x=0-3), add 1 to the number of states. Add 2 if it addresses a Peripheral SFR.
4. If this instruction addresses external memory location, add $N+2$ to the number of states ( $N$ : number of wait states).
5. If this instruction addresses external memory location, add $2(N+1)$ to the number of states ( $N$ : number of wait states).
6. If this instruction addresses external memory location, add $4(N+2)$ to the number of states ( $N$ : number of wait states).

Table 5.16. Summary of Bit Instructions

| Clear Bit |  | CLR <dest> | dest opnd $\leftarrow 0$ |  |  |  |

|  | WRj | Pop word register from stack | 3 | 5 | 2 | 4 |
|  | DRk | Pop double word register from stack | 3 | 9 | 2 | 8 |

## Notes:

1. A shaded cell denotes an instruction in the C51 Architecture.
2. If this instruction addresses an I/O Port (Px, x=0-3), add 1 to the number of states. Add 2 if it addresses a Peripheral SFR.
3. If this instruction addresses an I/O Port (Px, x=0-3), add 2 to the number of states. Add 3 if it addresses a Peripheral SFR.

Table 5.18. Summary of Conditional Jump Instructions (1/2)

| Jump conditional on status |  | Jcc rel <br> $(\mathrm{PC}) \leftarrow(\mathrm{PC})+$ size (instr); <br> IF [cc] THEN $(\mathrm{PC}) \leftarrow(\mathrm{PC})+$ rel |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Mnemonic | $\begin{aligned} & \langle\text { dest>, } \\ & \langle\operatorname{src}\rangle(1) \end{aligned}$ | Comments | Binary Mode ${ }^{(2)}$ |  | Source Mode ${ }^{(2)}$ |  |
|  |  |  | Bytes | States | Bytes | States |
| JC | rel | Jump if carry | 2 | $1 / 4^{(3)}$ | 2 | $1 / 4^{(3)}$ |
| JNC | rel | Jump if not carry | 2 | $1 / 4^{(3)}$ | 2 | $1 / 4{ }^{(3)}$ |
| JE | rel | Jump if equal | 3 | $2 / 5^{(3)}$ | 2 | $1 / 4^{(3)}$ |
| JNE | rel | Jump if not equal | 3 | $2 / 5^{(3)}$ | 2 | $1 / 4^{(3)}$ |
| JG | rel | Jump if greater than | 3 | $2 / 5^{(3)}$ | 2 | $1 / 4^{(3)}$ |
| JLE | rel | Jump if less than, or equal | 3 | 2/5 ${ }^{(3)}$ | 2 | $1 / 4{ }^{(3)}$ |
| JSL | rel | Jump if less than (signed) | 3 | $2 / 5^{(3)}$ | 2 | $1 / 4^{(3)}$ |
| JSLE | rel | Jump if less than, or equal (signed) | 3 | $2 / 5^{(3)}$ | 2 | $1 / 4{ }^{(3)}$ |
| JSG | rel | Jump if greater than (signed) | 3 | $2 / 5^{(3)}$ | 2 | $1 / 4^{(3)}$ |
| JSGE | rel | Jump if greater than or equal (signed) | 3 | 2/5 ${ }^{(3)}$ | 2 | $1 / 4^{(3)}$ |

Notes:

1. A shaded cell denotes an instruction in the C51 Architecture.
2. States are given as jump not-taken/taken.
3. In internal execution only, add 1 to the number of states of the 'jump taken' if the destination address is internal and odd.

Table 5.19. Summary of Conditional Jump Instructions (2/2)

[^1]Table 5.20. Summary of unconditional Jump Instructions

| Absolute jump Extended jump opnd |  | AJMP < src> | $\begin{aligned} & (\mathrm{PC}) \leftarrow(\mathrm{PC})+2 ;(\mathrm{PC})_{10: 0} \leftarrow \text { src opnd } \\ & (\mathrm{PC}) \leftarrow(\mathrm{PC})+\text { size }(\text { instr }) ;(\mathrm{PC})_{23: 0} \leftarrow \mathrm{src} \end{aligned}$ |  |  |  |

| :---: | :---: | :---: |
| 2 | ADD reg, op2 | All data addressing modes are supported. |
| 9 | SUB reg, op2 |  |
| B | CMP reg, op2 ${ }^{(1)}$ |  |
| 4 | ORL reg, op2 ${ }^{(2)}$ |  |
| 5 | ANL reg, op2 ${ }^{(2)}$ |  |
| 6 | XRL reg, op2 ${ }^{(2)}$ |  |
| 7 | MOV reg, op2 |  |
| 8 | DIV reg, op2 | $\begin{aligned} & \text { Two modes only: } \\ & \begin{aligned} \text { reg, op2 } & =\text { Rmd, Rms } \\ \text { reg, op2 } & =\mathrm{Wjd}, \mathrm{Wj} \end{aligned} \end{aligned}$ |
| A | MUL reg, op2 |  |

## Notes :

1. The CMP operation does not supPort DRk, direct 16 .
2. For the ORL, ANL and XRL operations, neither reg nor op2 can be DRk.

All of the bit instructions in the C251 Architecture (See Table 5.23. ) have opcode A9, which serves as an escape byte (similar to A5). The high nibble of byte 1 specifies the bit instruction, as given in Table 5.26.

Table 5.26. Bit Instructions

### 5.3. Instruction Set Summary

This section contains tables that summarize the instruction set. For each instruction there is a short description, its length in bytes, and its execution time in states.

## Notes:

- The instruction execution times given in the tables are for code executing from on-chip code memory and for data that is read from and written to on-chip RAM. Execution times are increased by executing code from external memory, accessing peripheral SFRs, accessing data in external memory, using wait states, or extending the ALE pulse.
- For some instructions, accessing the Port SFRs, Px, $x=0-3$, increases the execution time. These cases are noted individually in the tables.

### 5.3.1. Execution Times for Instructions that Access the Ports SFRs

The execution times for some instructions increases when the instruction accesses a Port SFR (Px, with $x=0-3$ ) as opposed to any other SFR. Table 5.34. lists these instructions and the execution times for Case 0 :

- Case 0: Code executes from on-chip ROM/OTPROM/EPROM and accesses locations in on-chip data RAM. The Port SFRs are not accessed.

In cases 1 to 4 , the instructions access a Port SFR :

- Case 1: Code executes from on-chip ROM/OTPROM/EPROM and accesses a Port SFR.
- Case 2: Code executes from external memory with no wait state and a short ALE (not extended) and accesses a Port SFR.
- Case 3: Code executes from external memory with one wait state and a short ALE (not extended) and accesses a Port SFR.
- Case 4: Code executes from external memory with one wait state and an extended ALE, and accesses a Port SFR.

The times for Cases 1 through 4 are expressed as the number of state times to add to the state times given for Case 0 .

Table 5.34. State Times to Access the Port SFRs

## Note :

1. A shaded cell denotes an instruction in the C51 Architecture.
2. If this instruction addresses an I/O Port (Px, x=3:0), add 1 to the number of states.
3. If this instruction addresses an I/O Port (Px, x=3:0), add 2 to the number of states.

### 5.4. Instruction Descriptions

This section describes each instruction in the C251 Architecture.
Table 5.44. defines the symbols ( $-, \vdash, 1,0, ?$ ) used to indicate the effect of the instruction on the flags in the PSW and PSW1 registers. For a conditional jump instruction, "!" indicates that a flag influences the decision to jump.

Table 5.44. Flag Symbols

| Symbol | Description |
| :---: | :--- |
| - | The instruction does not modify the flag. |
| $r$ | The instruction sets or clears the flag, as appropriate. |
| 1 | The instruction sets the flag. |
| 0 | The instruction clears the flag. |
| $?$ | The instruction leaves the flag in an indeterminate state. |
| $!$ | For a conditional jump instruction: the state of the flag before the instruction executes influences the <br> decision to jump or not jump. |

## ACALL <addr11>

## Function:

## Absolute call

## Description:

Unconditionally calls a subroutine at the specified address. The instruction increments the 3-byte PC twice to obtain the address of the following instruction, then pushes bytes 0 and 1 of the result onto the stack (byte 0 first) and increments the stack pointer twice. The destination address is obtained by successively concatenating bits 15-11 of the incremented PC, opcode bits 7-5, and the second byte of the instruction. The subroutine called must therefore start within the same 2-Kbyte "page" of the program memory as the first byte of the instruction following ACALL.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

The stack pointer (SP) contains 07h and the label "SUBRTN" is at program memory location 0345h. After executing the instruction ACALL SUBRTN at location 0123h, SP contains 09h; on-chip RAM locations 09 h and 08 h contain 01 h and 25 h , respectively; and the PC contains 0345 h .

## [Encoding]

| $\mathrm{a} 10\|\mathrm{a} 9\| \mathrm{a} 8 \mid 1$ | $\mathbf{1}$ | addr7-addr4 | addr3-addr0 |
| :--- | :--- | :--- | :--- |

## Hex Code in:

Binary Mode $=[$ Encoding $]$
Source Mode $=[$ Encoding $]$

## Operation:

ACALL
$(\mathrm{PC}) \leftarrow(\mathrm{PC})+2$
$(\mathrm{SP}) \leftarrow(\mathrm{SP})+1$
$((\mathrm{SP})) \leftarrow($ PC.7:0)
$(\mathrm{SP}) \leftarrow(\mathrm{SP})+1$
$((\mathrm{SP})) \leftarrow(\mathrm{PC} .15: 8)$
$($ PC. 10:0) $\leftarrow$ page address

## ADD <dest>,<src>

## Function:

Add

## Description:

Adds the source operand to the destination operand, which can be a register or the accumulator, leaving the result in the register or accumulator. If there is a carry out of bit 7 (CY), the CY flag is set. If byte variables are added, and if there is a carry out of bit 3 (AC), the AC flag is set. For addition of unsigned integers, the CY flag indicates that an overflow occurred.

If there is a carry out of bit 6 but not out of bit 7 , or a carry out of bit 7 but not bit 6 , the OV flag is set. When adding signed integers, the OV flag indicates a negative number produced as the sum of two positive operands, or a positive sum from two negative operands.
Bit 6 and bit 7 in this description refer to the most significant byte of the operand ( 8,16 or 32 bit)
Four source operand addressing modes are allowed: register, direct, register-indirect and immediate.

## FLAGS :

| $\mathbf{C Y}$ | AC | OV | $\mathbf{N}$ | $\mathbf{Z}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{r}$ |  |  |  |  |  |  |

## Example:

Register 1 contains 0 C 3 h (11000011B) and register 0 contains 0AAh (10101010B). After executing the instruction ADD R1,R0 register 1 contains 6Dh (01101101B), the AC flag is clear, and the CY and OV flags are set.

## ADDC A,<src>

## Function:

Add with carry

## Description:

Simultaneously adds the specified byte variable, the CY flag and the accumulator contents, leaving the result in the accumulator. If there is a carry out of bit 7 (CY), the CY flag is set; if there is a carry out of bit 3 (AC), the AC flag is set. When adding unsigned integers, the CY flag indicates that an overflow occurred.

If there is a carry out of bit 6 but not out of bit 7 , or a carry out of bit 7 but not bit 6 , the OV flag is set. When adding signed integers, the OV flag indicates a negative number produced as the sum of two positive operands, or a positive sum from two negative operands.

Bit 6 and bit 7 in this description refer to the most significant byte of the operand ( 8,16 or 32 bit)
Four source operand addressing modes are allowed: register, direct, register-indirect and immediate.
FLAGS :

| $\mathbf{C Y}$ | AC | OV | $\mathbf{N}$ | $\mathbf{Z}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $r$ | $\swarrow$ |  |  |  |  |  |

## Example :

The accumulator contains 0C3h (11000011B), register 0 contains 0AAh (10101010B) and the CY flag is set. After executing the instruction ADDC A,R0 the accumulator contains 6Eh ( 01101110 B ), the AC flag is clear and the CY and OV flags are set.

## AJMP addr11

## Function:

## Absolute jump

## Description:

Transfers program execution to the specified address, which is formed at run time by concatenating the upper five bits of the PC (after incrementing the PC twice), opcode bits 7-5, and the second byte of the instruction. The destination must therefore be within the same $2-$ Kbyte "page" of program memory as the first byte of the instruction following AJMP.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

The label "JMPADR" is at program memory location 0123h. After executing the instruction AJMP JMPADR at location 0345h the PC contains 0123h.
[Encoding]

| a10 $\|\mathrm{a} 9\| \mathrm{a} 8 \mid 0$ | $\mathbf{1}$ | addr7-addr4 | addr3-addr0 |
| :--- | :--- | :--- | :--- |

```
Hex Code in:
Binary Mode \(=[\) Encoding \(]\)
Source Mode \(=[\) Encoding \(]\)
```

## Operation:

AJMP
$(\mathrm{PC}) \leftarrow(\mathrm{PC})+2$
$($ PC.10:0) $\leftarrow$ page address

ANL <dest>,<src>

## Function:

Logical-AND

## Description:

Performs the bitwise logical-AND ( $\Lambda$ ) operation between the specified variables and stores the results in the destination variable.

The two operands allow 10 addressing mode combinations. When the destination is the register or accumulator, the source can use register, direct, register-indirect or immediate addressing; when the destination is a direct address, the source can be the accumulator or immediate data.

## Note :

When this instruction is used to modify an output Port, the value used as the original Port data is read from the output data latch, not the input pins.

FLAGS :

| $\mathbf{C Y}$ | AC | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | $\nearrow$ | $\nearrow$ |

## Example :

Register 1 contains 0 C 3 h (11000011B) and register 0 contains 55h (01010101B). After executing the instruction ANL R1, R0 register 1 contains 41h ( 01000001 B ).
When the destination is a directly addressed byte, this instruction clears combinations of bits in any RAM location or hardware register. The mask byte determining the pattern of bits to be cleared would either be an immediate constant contained in the instruction or a value computed in the register or accumulator at run time. The instruction ANL P1,\#01110011B clears bits 7, 3, and 2 of output Port 1.

## ANL CY,<src-bit>

## Function:

Logical-AND for bit variables

## Description:

If the boolean value of the source bit is a logical 0 , clear the CY flag; otherwise leave the CY flag in its current state. A slash (" $/$ ") preceding the operand in the assembly language indicates that the logical complement of the addressed bit is used as the source value, but the source bit itself is not affected.

Only direct addressing is allowed for the source operand.

## FLAGS

Operation:
ANL
$(\mathrm{CY}) \leftarrow(\mathrm{CY}) \Lambda \varnothing($ bit $)$

## CJNE <dest>,<src>,rel

## Function:

Compare and jump if not equal.

## Description:

Compares the magnitudes of the first two operands and branches if their values are not equal. The branch destination is computed by adding the signed relative displacement in the last instruction byte to the PC , after incrementing the PC to the start of the next instruction. If the unsigned integer value of <dest-byte> is less than the unsigned integer value of <src-byte>, the CY flag is set. Neither operand is affected.

The first two operands allow four addressing mode combinations: the accumulator may be compared with any directly addressed byte or immediate data and any indirect RAM location or working register can be compared with an immediate constant.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| 3 | - | - | 3 | 3 |

## Example :

The accumulator contains 34 h and R7 contains 56h. After executing the first instruction in the sequence

> CJNE R7,\#60h,NOT_EQ ;R7 = 60h ; . .

$$
\begin{array}{lll}
\text { NOT_EQ: JC } & \begin{array}{l}
\text { REQ_LOW } \\
\\
; R 7>60 \mathrm{~h}
\end{array} \quad ; \text { IF R7 < 60h }
\end{array}
$$

the CY flag is set and program execution continues at label NOT_EQ. By testing the CY flag, this instruction determines whether R7 is greater or less than 60 h .
If the data being presented to Port 1 is also 34 h , then executing the instruction, WAIT: CJNE A,P1,WAIT clears the CY flag and continues with the next instruction in the sequence, since the accumulator does equal the data read from Port 1. (If some other value was being input on Port 1, the program loops at this point until the Port 1 data changes to 34h.)

## CMP <dest>,<src>

## Function:

## Compare

## Description:

Subtracts the source operand from the destination operand. The result is not stored in the destination operand. If a borrow is needed for bit 7, the CY (borrow) flag is set; otherwise it is clear.

When subtracting signed integers, the OV flag indicates a negative result when a negative value is subtracted from a positive value, or a positive result when a positive value is subtracted from a negative value.

Bit 7 in this description refers to the most significant byte of the operand ( 8,16 or 32 bit)
The source operand allows four addressing modes: register, direct, immediate and indirect.

## FLAGS :

| $\mathbf{C Y}$ | AC | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |

## Example :

Register 1 contains 0C9h (11001001B) and register 0 contains 54h (01010100B). The instruction CMP R1,R0 clears the CY and AC flags and sets the OV flag.

## DA A

## Function:

Decimal-adjust accumulator for addition

## Description:

Adjusts the 8-bit value in the accumulator that resulted from the earlier addition of two variables (each in packed-BCD format), producing two 4-bit digits. Any ADD or ADDC instruction may have been used to perform the addition.
If accumulator bits 3:0 are greater than nine (XXXX1010-XXXX1111), or if the AC flag is set, six is added to the accumulator, producing the proper BCD digit in the low nibble. This internal addition sets the CY flag if a carry out of the lowest 4 bits propagated through all higher bits, but it does not clear the CY flag otherwise.
If the CY flag is now set or if the upper four bits now exceed nine (1010XXXX-1111XXXX), these four bits are incremented by six, producing the proper BCD digit in the high nibble. Again, this sets the CY flag if there was a carry out of the upper four bits, but does not clear the carry. The CY flag thus indicates if the sum of the original two BCD variables is greater than 100, allowing multiple-precision decimal addition. The OV flag is not affected.
All of this occurs during one instruction cycle. Essentially, this instruction performs the decimal conversion by adding $00 \mathrm{~h}, 06 \mathrm{~h}, 60 \mathrm{~h}$ or 66 h to the accumulator, depending on initial accumulator and PSW conditions.

## Note:

DA A cannot simply convert a Hexadecimal number in the accumulator to BCD notation, nor does DA A apply to decimal subtraction.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{r}$ | - | - | 3 | 3 |

## Example :

The accumulator contains $56 \mathrm{~h}(01010110 \mathrm{~B})$, which represents the packed BCD digits of the decimal number 56 . Register 3 contains 67 h ( 01100111 B ), which represents the packed BCD digits of the decimal number 67. The CY flag is set. After executing the instruction sequence ADDC A,R3.
DA A the accumulator contains 0BEh (10111110B) and the CY and AC flags are clear. The Decimal Adjust instruction then alters the accumulator to the value $24 \mathrm{~h}(00100100 \mathrm{~B})$, indicating the packed BCD digits of the decimal number 24 , the lower two digits of the decimal sum of 56, 67, and the carry-in. The CY flag is set by the Decimal Adjust instruction, indicating that a decimal overflow occurred. The true sum of 56,67 and 1 is 124 . BCD variables can be incremented or decremented by adding 01 h or 99 h . If the accumulator contains 30 h (representing the digits of 30 decimal), then the instruction sequence:

ADD A, \#99h.
DA A
leaves the CY flag set and 29 h in the accumulator, since $30+99=129$. The low byte of the sum can be interpreted to mean 30-1 = 29 .

## [Encoding]

## DIV <dest>,<src>

## Function:

Divide

## Description:

Divides the unsigned integer in the register by the unsigned integer operand in register addressing mode and clears the CY and OV flags.

For byte operands (<dest>,<src> = Rmd,Rms) the result is 16 bits. The 8 -bit quotient is stored in the higher byte of the word where Rmd resides; the 8 -bit remainder is stored in the lower byte of the word where Rmd resides. For example: register 1 contains 251 ( 0 FBh or 11111011 B ) and register 5 contains 18 ( 12 h or 00010010 B ). After executing the instruction DIV R1,R5 register 0 contains 13 ( 0 Dh or 00001101B); register 1 contains 17 (11h or 00010001B), since $251=(13 \times 18)+17$; and the CY and OV bits are clear (See Flags).

FLAGS : The CY flag is cleared. The N flag is set if the MSB of the quotient is set. The Z flag is set if the quotient is zero.:

| $\mathbf{C Y}$ | $\mathbf{A C}$ | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| 0 |  |  |  |  |

Exception: if <src> contains 00 h , the values returned in both operands are undefined; the CY flag is cleared, OV flag is set, and the rest of the flags are undefined.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| 0 | $?$ | 1 | $?$ | $?$ |

## DIV Rmd,Rms

## [Encoding]

| 1000 | 1100 | ssss | SSSS |
| :--- | :--- | :--- | :--- |

## Hex Code in:

Binary Mode $=[$ A5] [Encoding $]$
Source Mode $=$ [Encoding $]$

## Operation:

DIV (8-bit operands)
$($ Rmd $) \leftarrow$ remainder $($ Rmd $) /($ Rms $)$
if $\langle$ dest $\rangle \mathrm{md}=0,2,4, . ., 14$
$($ Rmd +1$) \leftarrow$ quotient $($ Rmd $) /($ Rms $)$
$($ Rmd -1$) \leftarrow$ remainder $($ Rmd $) /($ Rms $)$
if <dest> $\mathrm{md}=1,3,5, . ., 15$
$($ Rmd $) \leftarrow$ quotient $($ Rmd $) /($ Rms $)$

## DIV WRjd,WRjs

## [Encoding]

| 1000 | 1101 | tttt | TTTT |
| :--- | :--- | :--- | :--- |

## Hex Code in:

Binary Mode $=[$ A5][Encoding $]$
Source Mode $=[$ Encoding $]$

## Operation:

DIV (16-bit operands)
$($ WRjd $) \leftarrow$ remainder $(W R j d) /(W R j s)$
if <dest> jd $=0,4,8, \ldots 28$
$($ WRjd +2$) \leftarrow$ quotient $(W R j d) /(W R j s)$
$($ WRjd-2) $\leftarrow$ remainder $(W R j d) /(W R j s))$
if <dest> jd = 2, 6, 10, .. 30
$($ WRjd $) \leftarrow$ quotient $($ WRjd $) /($ WRjs

For example, for a destination register WR4, assume the quotient is 1122 h and the remainder is 3344 h . Then, the results are stored in these register file locations:

| Location | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6}$ | $\mathbf{7}$ |
| :---: | :---: | :---: | :---: | :---: |
| Contents | 33 h | 44 h | 11 h | 22 h |

## DIV AB

## Function:

Divide

## Description:

Divides the unsigned 8 -bit integer in the accumulator by the unsigned 8 -bit integer in register B . The accumulator receives the integer part of the quotient; register B receives the integer remainder. The CY and OV flags are cleared.
Exception: if register B contains 00 h , the values returned in the accumulator and register B are undefined; the CY flag is cleared and the OV flag is set.

## FLAGS :

| CY | AC | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| 0 | $r$ | $r$ | $r$ | $r$ |

For division by zero:

FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| 0 | $?$ | 1 | $?$ | $?$ |

## Example :

The accumulator contains 251 ( 0 FBh or 11111011B) and register B contains 18 ( 12 h or 00010010B). After executing the instruction DIV AB the accumulator contains 13 ( 0 Dh or 00001101B); register B contains 17 ( 11 h or 00010001B), since $251=(13 \times 18)+17$; and the CY and OV flags are clear.

## [Encoding]

$(\mathrm{B}) \leftarrow \operatorname{remainder}(\mathrm{A}) /(\mathrm{B})$

## DJNZ <byte>,<rel-addr>

## Function:

Decrement and jump if not zero

## Description:

Decrements the specified location by 1 and branches to the address specified by the second operand if the resulting value is not zero. An original value of 00 h underflows to 0 FFh . The branch destination is computed by adding the signed relative-displacement value in the last instruction byte to the PC, after incrementing the PC to the first byte of the following instruction.
The location decremented may be a register or directly addressed byte.

## Note :

When this instruction is used to modify an output Port, the value used as the original Port data is read from the output data latch, not the input pins.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| - | - | - |  |  |  |  |  |  |

## Example :

The on-chip RAM locations $40 \mathrm{~h}, 50 \mathrm{~h}$, and 60 h contain $01 \mathrm{~h}, 70 \mathrm{~h}$, and 15 h , respectively. After executing the following instruction sequence:

```
DJNZ 40h,LABEL1
DJNZ 50h,LABEL2
DJNZ 60h,LABEL
```

on-chip RAM locations $40 \mathrm{~h}, 50 \mathrm{~h}$, and 60 h contain $00 \mathrm{~h}, 6 \mathrm{Fh}$, and 15 h , respectively, and program execution continues at label LABEL2. (The first jump was not taken because the result was zero.)
This instruction provides a simple way of executing a program loop a given number of times, or for adding a moderate time delay (from 2 to 512 machine cycles) with a single instruction.
The instruction sequence,
TOGGLE :

| MOV | R2, \#8 |
| :--- | :--- |
| CPL | P1.7 |
| DJNZ | R2, TOGGLE |

toggles P1.7 eight times, causing four output pulses to appear at bit 7 of output Port 1. Each pulse lasts three states: two for DJNZ and one to alter the pin.

## ECALL <dest>

## Function:

Extended call

## Description:

Calls a subroutine located at the specified address. The instruction adds four to the program counter to generate the address of the next instruction and then PUSHes the 24-bit result onto the stack (high byte first), incrementing the stack pointer by three. The 8 bits of the high word and the 16 bits of the low word of the PC are then loaded, respectively, with the second, third and fourth bytes of the ECALL instruction. Program execution continues with the instruction at this address. The subroutine may therefore begin anywhere in the full 16-Mbyte memory space.

FLAGS :

| $\mathbf{C Y}$ | AC | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

The stack pointer contains 07 h and the label "SUBRTN" is assigned to program memory location 123456h. After executing the instruction ECALL SUBRTN at location 054321h, SP contains 0Ah; on-chip RAM locations 08h, 09h and 0 Ah contain $05 \mathrm{~h}, 43 \mathrm{~h}$ and 21 h , respectively; and the PC contains 123456 h .

## JB bit51,rel JB bit,rel

## Function:

Jump if bit set

## Description:

If the specified bit is a one, jump to the address specified; otherwise proceed with the next instruction. The branch destination is computed by adding the signed relative displacement in the third instruction byte to the PC , after incrementing the PC to the first byte of the next instruction. The bit tested is not modified.

FLAGS:

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

Input Port 1 contains 11001010B and the accumulator contains 56h ( 01010110 B ). After the instruction sequence:
JB P1.2,LABEL1
JB ACC.2,LABEL2
program execution continues at label LABEL2.

## Variations

## JBC bit51,rel JBC bit,rel

## Function:

Jump if bit is set and clear bit.

## Description:

If the specified bit is one, branch to the specified address; otherwise proceed with the next instruction. The bit is not cleared if it is already a zero. The branch destination is computed by adding the signed relative displacement in the third instruction byte to the PC, after incrementing the PC to the first byte of the next instruction.

## Note :

When this instruction is used to test an output pin, the value used as the original data is read from the output data latch, not the input pin.

## FLAGS :

| $\mathbf{C Y}$ | AC | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| $!$ | - | - | - | - |

## Example :

The accumulator contains 56h (01010110B). After the instruction sequence:

$$
\begin{aligned}
& \text { JBC ACC.3,LABEL1 } \\
& \text { JBC ACC.2,LABEL2 }
\end{aligned}
$$

the accumulator contains $52 \mathrm{~h}(01010010 \mathrm{~B})$ and program execution continues at label LABEL2.

JMP @ A+DPTR

## Function:

Jump indirect

## Description:

Adds the 8 -bit unsigned content of the accumulator with the 16 -bit data pointer and load the resulting sum into the lower 16 bits of the program counter. This is the address for subsequent instruction fetches. The contents of the accumulator and the data pointer are not affected.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

The accumulator contains an even number from 0 to 6 . The following sequence of instructions branchs to one of four AJMP instructions in a jump table starting at JMP_TBL :

| MOV | DPTR,\#JMP_TBL |
| :--- | :--- |
| JMP | @A+DPTR |
| AJMP | LABEL0 |
| AJMP | LABEL1 |
| AJMP | LABEL2 |
| AJMP | LABEL3 |

If the accumulator contains 04 h at the start this sequence, execution jumps to LABEL2. Remember that AJMP is a two-byte instruction, so the jump instructions start at every other address.

## [Encoding]

## LCALL <dest>

## Function:

## Long call

## Description:

Calls a subroutine located at the specified address. The instruction adds three to the program counter to generate the address of the next instruction and then PUSHes the 16-bit result onto the stack (low byte first). The stack pointer is incremented by two. The high and low bytes of the PC are then loaded, respectively, with the second and third bytes of the LCALL instruction. Program execution continues with the instruction at this address. The subroutine may therefore begin anywhere in the 64-Kbyte region of memory where the next instruction is located.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

The stack pointer contains 07 h and the label "SUBRTN" is assigned to program memory location 1234h. After executing the instruction LCALL SUBRTN at location 0123h, the stack pointer contains 09h, on-chip RAM locations 08h and 09 h contain 01 h and 26h and the PC contains 1234h.

## LCALL addr16

Operation:
LJMP
$($ PC $) \leftarrow$ (addr.15:0)

## LJMP @ WRj

## [Encoding]

| 1000 | 1001 | tttt | 0100 |
| :--- | :--- | :--- | :--- |

## Hex Code in:

Binary Mode $=[$ A5][Encoding]
Source Mode $=$ [Encoding]

## Operation:

LJMP
$(\mathrm{PC}) \leftarrow((\mathrm{WRj}))$

## MOV <dest>,<src>

## Function:

Move byte variable

## Description:

Copies the byte variable specified by the second operand into the location specified by the first operand. The source byte is not affected.

This is by far the most flexible operation. Twenty-four combinations of source and destination addressing modes are allowed.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

On-chip RAM location 30h contains 40h, on-chip RAM location 40h contains 10h, and input Port 1 contains 11001010B (0CAh). After executing the instruction sequence:

| MOV | R0,\#30h | $; \mathrm{R} 0<=30 \mathrm{~h}$ |
| :--- | :--- | :--- |
| MOV | A,@R0 | $; \mathrm{A}<=40 \mathrm{~h}$ |
| MOV | R1,A ;R1 | $<=40 \mathrm{~h}$ |
| MOV | B,@R1 | $; \mathrm{B}<=10 \mathrm{~h}$ |
| MOV | @R1,P1 | $; \mathrm{RAM}(40 \mathrm{~h})<=0 \mathrm{CAh}$ |
| MOV | P2,P1 ;P2 \#0CAh |  |

register 0 contains 30 h , the accumulator and register 1 contain 40 h , register B contains 10 h and on-chip RAM location 40h and output Port 2 contain 0CAh (11001010B).

## MOV <dest-bit>,<src-bit>

## Function

## Move bit data

## Description

Copies the boolean variable specified by the second operand into the location specified by the first operand. One of the operands must be the CY flag; the other may be any directly addressable bit. Does not affect any other register.

## FLAGS :

| $\mathbf{C Y}$ | AC | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{r}$ | - | - | - | - |

## Example :

The CY flag is set, input Port 3 contains 11001001B and output Port 1 contains 35 h ( 00110101 B ). After executing the instruction sequence:

MOV P1.3,CY
MOV CY,P3.3
MOV P1.2,CY
the CY flag is clear and Port 1 contains 39h (00111001B).

$(\mathrm{CY}) \leftarrow($ bit $)$

## MOV DPTR,\#data16

## Function:

Load data pointer with a 16-bit constant

## Description:

Loads the 16 -bit data pointer (DPTR) with the specified 16-bit constant. The high byte of the constant is loaded into the high byte of the data pointer (DPH). The low byte of the constant is loaded into the low byte of the data pointer (DPL).

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

After executing the instruction MOV DPTR,\#1234h DPTR contains 1234h (DPH contains 12h and DPL contains 34h).
[Encoding]

| 1001 | 0000 | immed data hi | immed data low |
| :--- | :--- | :--- | :--- |

## Hex Code in:

Binary Mode $=[$ Encoding $]$
Source Mode $=[$ Encoding $]$

## Operation:

MOV
$($ DPTR $) \leftarrow$ \#data16

## MOVC A,@A+<base-reg>

## Function:

Move code byte

## Description:

Loads the accumulator with a code byte or constant from program memory. The address of the byte fetched is the sum of the original unsigned 8 -bit accumulator contents and the contents of a 16-bit base register, which may be the 16 LSBs of the data pointer or PC. In the latter case, the PC is incremented to the address of the following instruction before being added with the accumulator; otherwise the base register is not altered. 16-bit addition is performed.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

The accumulator contains a number between 0 and 3 . The following instruction sequence translates the value in the accumulator to one of four values defined by the DB (define byte) directive.

| RELPC: | INC | A |
| :--- | :--- | :--- |
|  | MOVC | A, @ A+PC |
|  | RET |  |
|  | DB | 66 h |
|  | DB | 77 h |
|  | DB | 88 h |
|  | DB | 99 h |

If the subroutine is called with the accumulator equal to 01 h , it returns with 77 h in the accumulator. The INC A before the MOVC instruction is needed to "get around" the RET instruction above the table. If several bytes of code separated the MOVC from the table, the corresponding number would be added to the accumulator instead.

## MOVC A, @A+PC

## [Encoding]

| 1000 | 0011 |
| :--- | :--- |

## Hex Code in:

Binary Mode $=[$ Encoding $]$

$(\mathrm{A}) \leftarrow((\mathrm{A})+(\mathrm{PC}))$

## MOVC A,@A+DPTR

## [Encoding]

| 1001 | 0011 |
| :--- | :--- |

Hex Code in:<br>Binary Mode $=[$ Encoding $]$<br>Source Mode = [Encoding]

Operation:

MOVC
$(\mathrm{A}) \leftarrow((\mathrm{A})+(\mathrm{DPTR}))$

## MOVH DRk,\#data16

## Function:

Move immediate 16-bit data to the high word of a dword (double-word) register.

## Description:

Moves 16-bit immediate data to the high word of a dword (32-bit) register. The low word of the dword register is unchanged.

FLAGS :

| $\mathbf{C Y}$ | AC | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

The dword register DRk contains 5566 7788h. After the instruction MOVH DRk,\#1122h executes, DRk contains 1122 7788h.

## [Encoding]

| 0111 | 1010 | uuuu | 1100 | immed data hi | immed data low |
| :--- | :--- | :--- | :--- | :--- | :--- |

## Hex Code in:

Binary Mode =[A5] [Encoding]
Source Mode = [Encoding]

## Operation:

MOVH
(DRk).31-16 $\leftarrow$ \#data16

## MOVS WRj,Rm

## Function:

Move 8-bit register to 16-bit register with sign extension

## Description:

Moves the contents of an 8-bit register to the low byte of a 16-bit register. The high byte of the 16-bit register is filled with the sign extension, which is obtained from the MSB of the 8 - bit source register.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

8-bit register Rm contains 055 h ( 01010101 B ) and the 16 -bit register WRj contains 0 FFFFh (11111111 11111111B). The instruction MOVS WRj,Rm moves the contents of register Rm (01010101B) to register WRj (i.e., WRj contains 0000000001010101 B ).
[Encoding]

| 0001 | 1010 | tttt | ssss |
| :--- | :--- | :--- | :--- |

## Hex Code in:

Binary Mode $=[$ A5] [Encoding $]$
Source Mode $=$ [Encoding]

## Operation:

MOVS
(WRj).7-0 $\leftarrow($ Rm).7-0
(WRj).15-8 $\leftarrow$ MSB

## MOVX <dest>,<src>

## Function:

Move external

## Description:

Transfers data between the accumulator and a byte in external data RAM. There are two types of instructions. One provides an 8-bit indirect address to external data RAM; the second provides a 16-bit indirect address to external data RAM.

In the first type of MOVX instruction, the contents of R0 or R1 in the current register bank provides an 8-bit address on Port 0.8 bits are sufficient for external I/O expansion decoding or for a relatively small RAM array. For larger arrays, any Port pins can be used to output higher address bits. These pins would be controlled by an output instruction preceding the MOVX.
In the second type of MOVX instruction, the data pointer generates a 16-bit address. Port 2 outputs the upper 8 address bits (from DPH) while Port 0 outputs the lower 8 address bits (from DPL).
For both types of moves in nonpage mode, the data is multiplexed with the lower address bits on Port 0 . In page mode, the data is multiplexed with the contents of P2 on Port 2 ( 8 -bit address) or with the upper address bits on Port 2 (16-bit address).
It is possible in some situations to mix the two MOVX types. A large RAM array with its upper address lines driven by P2 can be addressed via the data pointer, or with code to output upper address bits to P2 followed by a MOVX instruction using R0 or R1.

FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

The TSC80251 Microcontroller is operating in nonpage mode. An external 256-byte RAM using multiplexed address/data lines (e.g., an Intel 8155 RAM/I/O/Timer) is connected to Port 0 . Port 3 provides control lines for the external RAM. Ports 1 and 2 are used for normal I/O. R0 and R1 contain 12h and 34h. Location 34h of the external RAM contains 56h. After executing the instruction sequence:

```
MOVX A,@R1
```

MOVX @R0,A
the accumulator and external RAM location 12 h contain 56 h .

## MOVX A,@DPTR

## MOVZ WRj,Rm

## Function:

Move 8-bit register to 16-bit register with zero extension

## Description:

Moves the contents of an 8-bit register to the low byte of a 16-bit register. The upper byte of the 16-bit register is filled with zeros.

FLAGS :

| $\mathbf{C Y}$ | AC | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

8-bit register Rm contains 055 h ( 01010101 B ) and 16-bit register WRj contains 0 FFFFh (11111111 11111111B). The instruction MOVZ WRj,Rm moves the contents of register Rm (01010101B) to register WRj. At the end of the operation, WRj contains 0000000001010101 B.

## [Encoding]

| 0000 | 1010 | tttt | ssss |
| :--- | :--- | :--- | :--- |

## Hex Code in:

Binary Mode $=[$ A5 $][$ Encoding $]$
Source Mode $=[$ Encoding $]$

Operation:
MOV
(WRj).7-0 $\leftarrow(\mathrm{Rm}) .7-0$
(WRj).15-8 $\leftarrow 0$

## MUL <dest>,<src>

## Function:

## Multiply

## Description:

Multiplies the unsigned integer in the source register with the unsigned integer in the destination register. Only register addressing is allowed.
For 8-bit operands, the result is 16 bits. The most significant byte of the result is stored in the low byte of the word where the destination register resides. The least significant byte is stored in the following byte register. The OV flag is set if the product is greater than $255(0 \mathrm{FFh})$; otherwise it is cleared.
For 16-bit operands, the result is 32 bits. The most significant word is stored in the low word of the the dword where the destination register resides. The least significant word is stored in the following word register. In this operation, the OV flag is set if the product is greater than 0FFFFh, otherwise it is cleared. The CY flag is always cleared. The N flag is set when the MSB of the result is set. The Z flag is set when the result is zero.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| 0 | - | $r$ | $\vdash$ | $r$ |

## Example :

Register R1 contains 80 ( 50 h or 10010000 B ) and register R0 contains 160 ( 0 A 0 h or 10010000 B ). After executing the instruction MUL R1,R0 which gives the product 12800 (3200h), register R0 contains 32h (00110010B), register R1 contains 00 h , the OV flag is set and the CY flag is clear.

## MUL Rmd,Rms

## [Encoding]

| 1010 | 1100 | ssss | SSSS |

## Operation:

MUL (16-bit operands)
if <dest> jd $=0,4,8, . ., 28$
WRjd $\leftarrow$ high word of the WRjd x WRjs
WRjd $+2 \leftarrow$ low word of the WRjd $x$ WRjs
if <dest> jd = 2, 6, 10, .., 30
WRjd- $2 \leftarrow$ high word of the WRjd x WRjs
WRjd $\leftarrow$ low word of the WRjd $x$ WRjs

## MUL AB

## Function:

Multiply

## Description:

Multiplies the unsigned 8 -bit integers in the accumulator and register B . The low byte of the 16 -bit product is left in the accumulator, and the high byte is left in register in B. If the product is greater than $255(0 \mathrm{FFh})$ the OV flag is set; otherwise it is clear. The CY flag is always clear.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| 0 | - | $r$ | $r$ | $\gamma$ |

## Example :

The accumulator contains $80(50 \mathrm{~h})$ and register B contains 160 (0A0h). After executing the instruction MUL AB which gives the product $12800(3200 \mathrm{~h})$, register B contains $32 \mathrm{~h}(00110010 \mathrm{~B})$, the accumulator contains 00 h , the OV flag is set and the CY flag is clear.

## [Encoding]

| 1010 | 0100 |
| :--- | :--- |

## Hex Code in:

Binary Mode $=[$ Encoding $]$
Source Mode $=[$ Encoding $]$

## Operation:

MUL
(A) $\leftarrow$ low byte of (A) X (B)
$(\mathrm{B}) \leftarrow$ high byte of $(\mathrm{A}) \mathrm{X}(\mathrm{B})$

## Function:

No operation

## Description:

Execution continues at the following instruction. Affects the PC register only.

## FLAGS :

| $\mathbf{C Y}$ | AC | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

We assume we are executing an internal code and you want to produce a low-going output pulse on bit 7 of Port 2 that lasts exactly 11 states. A simple CLR-SETB sequence generates an eight-state pulse. (Each instruction requires four states to write to a Port SFR.) You can insert three additional states (if no interrupts are enabled) with the following instruction sequence :

CLR P2.7
NOP
NOP
NOP
SETB P2.7

## [Encoding]

| 0000 | 0000 |
| :--- | :--- |

## Hex Code in:

Binary Mode = [Encoding]
Source Mode $=$ [Encoding $]$

## Operation:

NOP
$(\mathrm{PC}) \leftarrow(\mathrm{PC})+1$

## ORL <dest> <src>

## Function:

## Logical-OR for byte variables

## Description:

Performs the bitwise logical-OR operation (V) between the specified variables, storing the results in the destination operand.

The destination operand can be a register, an accumulator or direct address.
The two operands allow twelve addressing mode combinations. When the destination is the accumulator, the source can be register, direct, register-indirect or immediate addressing; when the destination is a direct address, the source can be the accumulator or immediate data. When the destination is register the source can be register, immediate, direct and indirect addressing.

## Note:

When this instruction is used to modify an output Port, the value used as the original Port data is read from the output data latch, not the input pins.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | $r$ | $r$ |

## Example :

The accumulator contains 0C3h (11000011B) and R0 contains 55h (01010101B). After executing the instruction, ORL A, R0 the accumulator contains 0D7h (11010111B).
When the destination is a directly addressed byte, the instruction can set combinations of bits in any RAM location or hardware register. The pattern of bits to be set is determined by a mask byte, which may be a constant data value in the instruction or a variable computed in the accumulator at run time. After executing the instruction ORL P1, \#00110010B sets bits 5, 4 and 1 of output Port 1 .

## POP <src>

## Function:

Pop from stack.

## Description:

Reads the contents of the on-chip RAM location addressed by the stack pointer, then decrements the stack pointer by one. The value read at the original RAM location is transferred to the newly addressed location, which can be 8-bit or 16-bit.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

The stack pointer contains 32 h and on-chip RAM locations 30 h through 32 h contain 01 h , 23 h , and 20 h , respectively. After executing the instruction sequence:

> POP DPH

POP DPL
the stack pointer contains 30h and the data pointer contains 0123 h . After executing the instruction POP SP the stack pointer contains 20 h . Note that in this special case the stack pointer was decremented to 2 Fh before it was loaded with the value popped (20h).

## RET

## Function:

Return from subroutine

## Description:

Pops the high and low bytes of the PC successively from the stack, decrementing the stack pointer by two. Program execution continues at the resulting address, which normally is the instruction immediately following ACALL or LCALL.

FLAGS :

| $\mathbf{C Y}$ | AC | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

The stack pointer contains 0 Bh and on-chip RAM locations 0 Ah and 0 Bh contain 01 h and 23 h , respectively. After executing the instruction, RET the stack pointer contains 09 h and program execution continues at location 0123 h .

## [Encoding]

| 0010 | 0010 |
| :--- | :--- |

## Hex Code in:

Binary Mode $=[$ Encoding $]$
Source Mode $=[$ Encoding $]$

Operation:
RET
(PC). 15:8 $\leftarrow((\mathrm{SP}))$
$(\mathrm{SP}) \leftarrow(\mathrm{SP})-1$
(PC).7:0 $\leftarrow((\mathrm{SP}))$
$(\mathrm{SP}) \leftarrow(\mathrm{SP})-1$

## RETI

## Function:

## Return from interrupt

## Description:

This instruction pops two or four bytes from the stack, depending on the INTR bit in the CONFIG1 register .
If INTR $=0$, RETI pops the high and low bytes of the PC successively from the stack and uses them as the 16-bit return address in region FF:.The stack pointer is decremented by two. No other registers are affected, and neither PSW nor PSW1 is automatically restored to its pre-interrupt status.
If INTR $=1$, RETI pops four bytes from the stack: PSW1 and the three bytes of the PC. The three bytes of the PC are the return address, which can be anywhere in the 16-Mbyte memory space. The stack pointer is decremented by four. PSW1 is restored to its pre-interrupt status, but PSW is not restored to its pre-interrupt status. No other registers are affected.
For either value of INTR, hardware restores the interrupt logic to accept additional interrupts at the same priority level as the one just processed. Program execution continues at the return address, which normally is the instruction immediately after the point at which the interrupt request was detected. If an interrupt of the same or lower priority is pending when the RETI instruction is executed, that one instruction is executed before the pending interrupt is processed.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

$\operatorname{INTR}=0$. The stack pointer contains 0 Bh. An interrupt was detected during the instruction ending at location 0122 h . On-chip RAM locations 0Ah and 0 Bh contain 01 h and 23 h , respectively. After executing the instruction, RETI the stack pointer contains 09 h and program execution continues at location 0123 h .

## RL A

## Function:

Rotate accumulator left

## Description:

Rotates the 8 bits in the accumulator one bit to the left. Bit 7 is rotated into the bit 0 position.

## FLAGS :

| $\mathbf{C Y}$ | AC | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | $\gamma$ | $\gamma$ |

## Example :

The accumulator contains $0 \mathrm{C} 5 \mathrm{~h}(11000101 \mathrm{~B})$. After executing the instruction, RL A the accumulator contains 8Bh (10001011B); the CY flag is unaffected.

## [Encoding]

## Operation:

RL
(A) $\cdot \mathrm{a}+1 \leftarrow$ (A). a
(A). $0 \leftarrow$ (A). 7

## RLC A

## Function:

Rotate accumulator left through the carry flag

## Description:

Rotates the 8 bits in the accumulator and the CY flag one bit to the left. Bit 7 moves into the CY flag position and the original state of the CY flag moves into bit 0 position.

## Description:

FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{\gamma}$ | - | - | $\nearrow$ | $\nearrow$ |

## Example :

The accumulator contains 0C5h (11000101B) and the CY flag is clear. After executing the instruction RLC A the accumulator contains 8Ah (10001010B) and the CY flag is set.

SETB <bit>

## Function:

Set bit

## Description:

Sets the specified bit to one. SETB can operate on the CY flag or any directly addressable bit.
FLAGS : No flags are affected except the CY flag for instruction with CY as the operand.

| $\mathbf{C Y}$ | AC | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{r}$ | - | - | - | - |

## Example:

The CY flag is clear and output Port 1 contains 34h (00110100B). After executing the instruction sequence:
SETB CY
SETB P1.0
the CY flag is set and output Port 1 contains 35 h (00110101B).

## SETB bit51

## Operation:

SETB
(bit) $\leftarrow 1$

## S.JMP rel

## Function:

Short jump

## Description:

Program control branches unconditionally to the specified address. The branch destination is computed by adding the signed displacement in the second instruction byte to the PC, after incrementing the PC twice. Therefore, the range of destinations allowed is from 128 bytes preceding this instruction to 127 bytes following it.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | - | - |

## Example :

The label "RELADR" is assigned to an instruction at program memory location 0123h. The instruction SJMP RELADR assembles into location 0100h. After executing the instruction, the PC contains 0123h.

## Note :

In the above example, the instruction following SJMP is located at 102h. Therefore, the displacement byte of the instruction is the relative offset $(0123 h-0102 h)=21 h$. Put another way, an SJMP with a displacement of OFEh would be a one-instruction infinite loop.

## [Encoding]

## SUB <dest>,<src>

## Function:

Subtract

## Description:

Subtracts the specified variable from the destination operand, leaving the result in the destination operand. SUB sets the CY (borrow) flag if a borrow is needed for bit 7. Otherwise, CY is clear.
When subtracting signed integers, the OV flag indicates a negative number produced when a negative value is subtracted from a positive value, or a positive result when a positive number is subtracted from a negative number.
Bit 7 in this description refers to the most significant byte of the operand ( 8,16 , or 32 bit)
The source operand allows four addressing modes: immediate, indirect, register and direct.
FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | $\mathbf{O V}$ | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{\gamma}$ | $\boldsymbol{*}$ | $\boldsymbol{r}$ | $\boldsymbol{\gamma}$ |  |

丸 For word and dword subtractions, AC is not affected.

## Example :

Register 1 contains 0C9h (11001001B) and register 0 contains 54h (01010100B). After executing the instruction SUB $\mathrm{R} 1, \mathrm{R} 0$ register 1 contains $75 \mathrm{~h}(01110101 \mathrm{~B})$, the CY and AC flags are clear, and the OV flag is set.

## SUBB A,<src-byte>

## Function:

Subtract with borrow

## Description:

SUBB subtracts the specified variable and the CY flag together from the accumulator, leaving the result in the accumulator. SUBB sets the CY (borrow) flag if a borrow is needed for bit 7 and clears CY otherwise. (If CY was set before executing a SUBB instruction, this indicates that a borrow was needed for the previous step in a multiple precision subtraction, so the CY flag is subtracted from the accumulator along with the source operand.) AC is set if a borrow is needed for bit 3 and cleared otherwise. OV is set if a borrow is needed into bit 6 , but not into bit 7 , or into bit 7 , but not bit 6 .

When subtracting signed integers the OV flag indicates a negative number produced when a negative value is subtracted from a positive value or a positive result when a positive number is subtracted from a negative number.
Bit 6 and bit 7 in this description refer to the most significant byte of the operand ( 8,16 or 32 bit)
The source operand allows four addressing modes: register, direct, register-indirect or immediate.

## FLAGS :

| $\mathbf{C Y}$ | $\mathbf{A C}$ | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |

## Example :

The accumulator contains $0 \mathrm{C} 9 \mathrm{~h}(11001001 \mathrm{~B})$, register 2 contains $54 \mathrm{~h}(01010100 \mathrm{~B})$, and the CY flag is set. After executing the instruction SUBB A,R2 the accumulator contains 74h (01110100B), the CY and AC flags are clear, and the OV flag is set.Notice that 0 C 9 h minus 54 h is 75 h . The difference between this and the above result is due to the CY (borrow) flag being set before the operation. If the state of the carry is not known before starting a single or multiple-precision subtraction, it should be explicitly cleared by a CLR CY instruction.

Logical Exclusive-OR for byte variables

## Description:

Performs the bitwise logical Exclusive-OR operation $(\forall)$ between the specified variables, storing the results in the destination. The destination operand can be the accumulator, a register or a direct address.

The two operands allow 12 addressing mode combinations. When the destination is the accumulator or a register, the source addressing can be register, direct, register-indirect or immediate; when the destination is a direct address, the source can be the accumulator or immediate data.

## Note :

When this instruction is used to modify an output Port, the value used as the original Port data is read from the output data latch, not the input pins.

FLAGS :

| $\mathbf{C Y}$ | AC | OV | $\mathbf{N}$ | $\mathbf{Z}$ |
| :---: | :---: | :---: | :---: | :---: |
| - | - | - | $V$ | $\nu$ |

## Example :

The contains 0C3h (11000011B) and R0 contains 0AAh (10101010B). After executing the instruction, XRL A,R0 the accumulator contains 69h (01101001B).

When the destination is a directly addressed byte, this instruction can complement combinations of bits in any RAM location or hardware register. The pattern of bits to be complemented is then determined by a mask byte, either a constant contained in the instruction or a variable computed in the accumulator at run time. The instruction XRL P1,\#00110001B complements bits 5, 4, and 0 of output Port 1.

## Glossary

This glossary defines acronyms, abbreviations, and terms that have special meaning in this manual.

| \#0data16 | A 32-bit constant that is immediately addressed in an instruction. The upper 16-bit part is filled with zeros. |
| :---: | :---: |
| \#1data16 | A 32-bit constant that is immediately addressed in an instruction. The upper 16-bit part is filled with ones. |
| \#data An | 8-bit constant that is immediately addressed in an instruction. |
| \#data16 | A 16-bit constant that is immediately addressed in an instruction. |
| \#short | A constant, equal to 1,2 or 4 , that is immediately addressed in an instruction. |
| accumulator | A register or storage location that forms the result of an arithmetic or logical operation. |
| addr 11 | An 11-bit destination address. The destination can be anywhere within the same $2-$ Kbyte block of memory as the first byte of the next instruction. |
| addr16 | A 16-bit destination address. The destination can be anywhere within the same $64-$ Kbyte region as the first byte of the next instruction. |
| addr24 | A 24-bit destination address. The destination can be anywhere within the 16-Mbyte address space. |
| ALU | Arithmetic-logic unit. The part of the CPU that processes arithmetic and logical operations. |
| assert | The term assert refers to the act of making a signal active (enabled). The polarity (high/low) is defined by the signal name. Active-low signals are designated by a pound symbol (\#) suffix; active-high signals have no suffix. To assert RD\# is to drive it low; to assert ALE is to drive it high. |
| binary-code compatibility | The ability of a TSC80251 microcontroller to execute, without modification, binary code written for an 80C51 microcontroller. |
| binary mode | An operating mode, selected by a configuration bit, that enables a TSC80251 microcontroller to execute, without modification, binary code written for a 80C51 microcontroller. |
| bit | A binary digit. |
| bit (operand) | An addressable bit in the C251 Architecture. |
| bit51 | An addressable bit in the C251 Architecture. |
| byte | Any 8-bit unit of data. |

| clear | The term clear refers to the value of a bit or the act of giving it a value. If a bit is clear, its value is " 0 "; clearing a bit gives it a " 0 " value. |
| :---: | :---: |
| code memory | See program memory. |
| configuration bytes | Bytes that determine a set of operating parameters for the TSC80251 Product. For TSC80251 EPROM and OTPROM versions, these bytes are programmable in an EPROM area. For TSC83251 masked ROM versions, these bytes are additional information provided in a masked ROM area. For TSC80251 ROMless version, these bytes are configured in factory according to the part number. |
| dir8 | An 8-bit direct address. This can be a memory address or an SFR address. |
| dir16 | A 16-bit memory address (00:0000h-00:FFFFh) used in direct addressing. |
| DPTR | The 16-bit data pointer. In TSC80251 microcontrollers, DPTR is the lower 16 bits of the 24 -bit extended data pointer, DPX. |
| DPX | The 24-bit extended data pointer in TSC80251 microcontrollers. See also DPTR. |
| deassert | The term deassert refers to the act of making a signal inactive (disabled). The polarity (high/low) is defined by the signal name. Active-low signals are designated by a pound symbol (\#) suffix; active-high signals have no suffix. To deassert RD\# is to drive it high; to deassert ALE is to drive it low. |
| double word | A 32-bit unit of data. In memory, a double word comprises four contiguous bytes. |
| dword | See double word. |
| EPROM | Erasable programmable read-only memory. |
| external address | A 16-bit or 17-bit address presented on the device pins. The address decoded by an external device depends on how many of these address bits the external system uses. See also internal address. |
| integer | Any member of the set consisting of the positive and negative whole numbers and zero. |
| internal address | The 24-bit address that the device generates. See also external address. |
| interrupt handler | The module responsible for handling interrupts that are to be serviced by user-written interrupt service routines. |
| interrupt latency | The delay between an interrupt request and the time when the first instruction in the interrupt service routine begins execution. |
| interrupt response time | The time delay between an interrupt request and the resulting break in the current instruction stream. |
| interrupt service routine | The software routine that services an interrupt. |
| LSB | Least-significant bit of a byte or a least-significant byte of a word. |
| MSB | Most-significant bit of a byte or a most-significant byte of a word. |

| multiplexed bus | A bus on which the data is time-multiplexed with (some of) the address bits. |
| :--- | :--- |
| OTPROM | One-time-programmable read-only memory, a version of EPROM. |
| PC | Program counter. |
| program memory | A part of memory where instructions can be stored for fetching and execution. |
| RAM | Random access memory |
| rel | A signed (two's complement) 8-bit, relative destination address. The destination <br> is -128 to +127 bytes relative to the first byte of the next instruction. |
| reserved bits | Register bits that are not used in this device but may be used in future <br> implementations. Avoid any software dependence on these bits. In most cases: the <br> value read from this bit is indeterminate; do not set this bit. |
| ROM | Read only memory |
| set | The term set refers to the value of a bit or the act of giving it a value. If a bit is set, |
| its value is "1"; setting a bit gives it a "1" value. |  |A 16-bit unit of data. In memory, a word comprises two contiguous bytes.

[^0]:    Notes:

    1. If this instruction addresses an I/O Port (Px, x=0-3), add 1 to the number of states. Add 2 if it addresses a Peripheral SFR.
    2. If this instruction addresses external memory location, add $N+2$ to the number of states ( $N$ : number of wait states).
    3. If this instruction addresses external memory location, add $2(N+2)$ to the number of states ( $N$ : number of wait states).
[^1]:    Notes:

    1. A shaded cell denotes an instruction in the C51 Architecture.
    2. States are given as jump not-taken/taken.
    3. If this instruction addresses an I/O Port (Px, x=0-3), add 1 to the number of states. Add 2 if it addresses a Peripheral SFR.
    4. If this instruction addresses an I/O Port (Px, x=0-3), add 2 to the number of states. Add 3 if it addresses a Peripheral SFR.
    5. If this instruction addresses an I/O Port (Px, x=0-3), add 3 to the number of states. Add 5 if it addresses a Peripheral SFR.
    6. In internal execution only, add 1 to the number of states of the 'jump taken' if the destination address is internal and odd.
[^2]:    Note :

    1. A shaded cell denotes an instruction in the C51 Architecture.
    2. If this instruction addresses an I/O Port (Px, x=3:0), add 1 to the number of states.
