Document Number: MC34709 Rev. 1.0, 8/2012

Power Management Integrated Circuit (PMIC) for i.MX50/53 Families

The 34709 is the Power Management Integrated Circuit (PMIC) designed primarily for use with the Freescale i.MX50 and i.MX53 families. It offers a lower cost alternative to the MC34708, targeting embedded applications that do not require a battery charger. However, it can be easily combined with an external charger, allowing flexibility for either single or multi-cell Li-Ion battery configurations. It supports both consumer and industrial applications with a single 130-pin 8x8 MAPBGA 0.5 mm pitch package that is easily routable in low cost board designs.

Features

- Five buck converters configurable to provide up to six independent outputs for direct supply of the processor core, memory, and peripherals.
- · Boost regulator for USB PHY domain on i.MX processors.
- Seven LDO regulators with internal and external pass devices for thermal budget optimization
- One low current, high accuracy, voltage reference for DDR memory
- · 10-bit ADC for monitoring battery and other inputs
- Real time clock and crystal oscillator circuitry with a coin cell backup/charger
- SPI/I²C bus for control and register interface
- · Four general purpose low-voltage I/Os with interrupt capability
- Two PWM outputs

1 Orderable Parts

This section describes the part numbers available to be purchased, along with their differences. Valid orderable part numbers are provided on the web. To determine the orderable part numbers for this device, go to http://www.freescale.com and perform a part number search for the following device numbers.

Table 1. Orderable Part Variations

| Part Number ⁽¹⁾ | Temperature (T _A) | Package |
|----------------------------|-------------------------------|--|
| PC34709VK | -40 to 85 °C | 130 MAPBGA - 8.0 x 8.0 mm - 0.5 mm Pitch |

Notes

1. To Order parts in Tape & Reel, add the R2 suffix to the part number.

2 Part Identification

This section provides an explanation of the part numbers and their alpha numeric breakdown.

2.1 Description

Part numbers for the chips have fields that identify the specific part configuration. You can use the values of these fields to determine the specific part you have received.

2.2 Format and Examples

Part numbers for a given device have the following format, followed by a device example:

```
Table 2 - Part Numbering - Analog:
```

PC tt xxx r v PPP RR - PC34709VKR2

2.3 Fields

These tables list the possible values for each field in the part number (not all combinations are valid).

| Table 2: Part Numbering - Analog | Table 2: | Part | Numbering | - Analog |
|----------------------------------|----------|------|-----------|----------|
|----------------------------------|----------|------|-----------|----------|

| FIELD | DESCRIPTION | VALUES | | | | | |
|-------|-------------------------|--|--|--|--|--|--|
| PC | Product Category | MC- Qualified Standard PC- Prototype Device | | | | | |
| tt | Temperature Range | • 33 = -40 °C to > 105 °C • 34 = -40 °C to ≤ 105 °C • 35 = -55 °C to ≥ 125 °C | | | | | |
| ххх | Product Number | Assigned by Marketing | | | | | |

5 General Product Characteristics

5.1 Maximum Ratings

Table 4. Maximum Ratings

All voltages are with respect to ground, unless otherwise noted. Exceeding these ratings may cause a malfunction or permanent damage to the device.

| Symbol | Description (Rating) | Min. | Max. | Unit | Notes |
|---------------------|---|------|-------|------|-------|
| | RATINGS | | | | |
| VICTEST | ICTEST Pin Voltage | - | 1.8 | V | |
| V _{BP} | BP Voltage | - | 4.5 | V | |
| V _{LICELL} | Coin Cell Voltage | - | 3.6 | V | |
| V _{ESD} | ESD Ratings Human Body Model All pins | - | ±2000 | V | (2) |
| 200 | Charge Device Model All pins | - | ±500 | | (2) |

Notes

Г

 ESD testing is performed in accordance with the Human Body Model (HBM) (C_{ZAP} = 100 pF, R_{ZAP} = 1500 Ω), and the Charge Device Model (CDM), Robotic (C_{ZAP} = 4.0 pF).

5.2 Thermal Characteristics

Table 5. Thermal Ratings

All voltages are with respect to ground, unless otherwise noted. Exceeding these ratings may cause a malfunction or permanent damage to the device.

| Symbol | Description (Rating) | Min. | Max. | Unit | Notes |
|-------------------|---|------|------------|------|----------|
| THERMAL RAT | INGS | | | | |
| T _A | Ambient Operating Temperature Range | - | -40 to 85 | °C | |
| TJ | Operating Junction Temperature Range | | -40 to 125 | °C | |
| T _{ST} | Storage Temperature Range | | -65 to 150 | °C | |
| T _{PPRT} | Peak Package Reflow Temperature During Reflow | - | Note 3 | °C | (3), (4) |

THERMAL RESISTANCE AND PACKAGE DISSIPATION RATINGS

| R _{θJA} | Junction to Ambient Natural Convection Single layer board (1s) | - | 93 | °C/W | (5), (6) |
|-------------------|--|---|----|------|----------|
| R _{θJMA} | Junction to Ambient Natural Convection Four layer board (2s2p) | - | 53 | °C/W | (5), (7) |
| R _{θJMA} | Junction to Ambient (@200 ft/min.) Single layer board (1s) | - | 80 | °C/W | (5), (7) |
| R _{θJMA} | Junction to Ambient (@200 ft/min.) Four layer board (2s2p) | - | 49 | °C/W | (5), (7) |
| R _{θJB} | Junction to Board | - | 34 | °C/W | (8) |
| R _{θJC} | Junction to Case | - | 25 | °C/W | (9) |

Table 5. Thermal Ratings (continued)

All voltages are with respect to ground, unless otherwise noted. Exceeding these ratings may cause a malfunction or permanent damage to the device.

| Symbol | Description (Rating) | Min. | Max. | Unit | Notes |
|--|--|------|------|------|-------|
| THERMAL RESISTANCE AND PACKAGE DISSIPATION RATINGS (CONTINUED) | | | | | |
| ΨJT | Junction to Package Top Natural Convection | - | 6.0 | °C/W | (10) |

Notes

- 3. Pin soldering temperature limit is for 10 seconds maximum duration. Not designed for immersion soldering. Exceeding these limits may cause a malfunction or permanent damage to the device.
- 4. Freescale's Package Reflow capability meets the Pb-free requirements for JEDEC standard J-STD-020C, for Peak Package Reflow Temperature and Moisture Sensitivity Levels (MSL).
- 5. Junction temperature is a function of on-chip power dissipation, package thermal resistance, mounting site (board) temperature, ambient temperature, air flow, power dissipation of other components on the board, and board thermal resistance.
- 6. Per JEDEC JESD51-2 with the single layer board horizontal. Board meets JESD51-9 specification.
- 7. Per JEDEC JESD51-6 with the board horizontal.
- 8. Thermal resistance between the die and the printed circuit board per JEDEC JESD51-8. Board temperature is measured on the top surface of the board near the package.
- 9. Thermal resistance between the die and the case top surface as measured by the cold plate method (MIL SPEC-883 Method 1012.1).
- 10. Thermal characterization parameter indicating the temperature difference between package top and the junction temperature per JEDEC JESD51-2. When Greek letters are not available, the thermal characterization parameter is written as Psi-JT.

5.2.1 Power Dissipation

During operation, the temperature of the die should not exceed the maximum junction temperature. To optimize the thermal management scheme and avoid overheating, the 34709 PMIC provides a thermal management system. The thermal protection is based on a circuit with a voltage output that is proportional to the absolute temperature. This voltage can be read out via the ADC for specific temperature readouts, see Serial Interfaces.

This voltage is monitored by an integrated comparator. Interrupts THERM110, THERM120, THERM125, and THERM130 will be generated when respectively crossing in either direction of the thresholds specified in <u>Table 6</u>. The temperature range can be determined by reading the THERM125.

Thermal protection is integrated to power off the 34709 PMIC, in case of over dissipation. This thermal protection will act above the maximum junction temperature to avoid any unwanted power downs. The protection is debounced for 8.0 ms in order to suppress any (thermal) noise. This protection should be considered as a fail-safe mechanism and therefore the application design should be dimensioned such that this protection is not tripped under normal conditions. The temperature thresholds and the sense bit assignment are listed in <u>Table 6</u>.

Table 6. Thermal Protection Thresholds

| Parameter | Min | Тур | Max | Units | Notes |
|-------------------------------------|-----|-----|-----|-------|-------|
| Thermal 110 °C threshold (THERM110) | 105 | 110 | 115 | °C | |
| Thermal 120 °C threshold (THERM120) | 115 | 120 | 125 | °C | |
| Thermal 125 °C threshold (THERM125) | 120 | 125 | 130 | °C | |
| Thermal 130 °C threshold (THERM130) | 125 | 130 | 135 | °C | |
| Thermal warning hysteresis | 2.0 | - | 4.0 | °C | (11) |
| Thermal protection threshold | 130 | 140 | 150 | °C | |

Notes

11. Equivalent to approx. 30 mW min, 60 mW max

5.3 Electrical Characteristics

5.3.1 General PMIC Specifications

Table 7. General Electrical Characteristic

Notes

12. SPIVCC is typically connected to the output of buck regulator SW5 and set to 1.800 V

13. Input has internal pull-up to VCOREDIG equivalent to 200 kOhm

14. Input state is latched in first phase of cold start, refer to Serial Interfaces for a description of the PUMS configuration

15. Input state is not latched

16. A weak pull-down represents a nominal internal pull-down of 100 nA, unless otherwise noted

17. RESETB, RESETBMCU, SDWNB, SW1PWGD, SW2PWGD have open-drain outputs, external pull-ups are required

18. SPIVCC needs to remain enabled for proper detection of WDI High to avoid involuntary shutdown

19. The maximum should never exceed the maximum rating of the pin as given in Pin Connections

20. The weak pull-down on CS is disabled if a VIH is detected at start-up to avoid extra consumption in I²C mode

21. The output drive strength is programmable

5.3.2 Current Consumption

The current consumption of the individual blocks is described in detail throughout this specification. For convenience, a summary table follows for standard use cases.

Table 8. Current Consumption Summary ⁽²⁴⁾

Characteristics noted under conditions BP = 3.6 V, -40 °C \leq T_A \leq 85 °C, unless otherwise noted. Typical values at BP = 3.6 V and T_A = 25 °C under nominal conditions, unless otherwise noted.

| Mode | Description | Тур | Мах | Unit | Notes |
|-----------------------|---|-----|-----|------|-------|
| | All blocks disabled, BP=0, coin cell is attached to LICELL (at 25 °C only) | | | | |
| RTC / Power cut | RTC Logic VCORE Module VSRTC 32 k Oscillator Clk32KMCU buffer active(10 pF load) | 4.0 | 7.0 | μΑ | |
| OFF (good battery) | All blocks disabled, BP>3.0 V(at 25 °C only) • Digital Core • RTC Logic • VCORE Module • VSRTC • 32 k Oscillator • CLK32KMCU buffer active (10 pF load) • COINCHEN = 0 | 20 | 55 | μΑ | |
| ON Standby | Low-power Mode (Standby pin asserted and ON_STBY_LP=1) Digital core RTC logic VCORE module VSRTC CLK32KMCU/CLK32K active (10 pF load) 32 k oscillator I_{REF} SW1, SW2, SW3, SW4A, SW4B, SW5 in PFM ^{(23),(27)} VDDREF, VPLL, VGEN1, VGEN2, VUSB2, VDAC in low-power mode ^{(22),(25)} | 260 | 650 | μΑ | |
| ON Standby | Digital core RTC logic VCORE module VSRTC CLK32KMCU/CLK32K active (10 pF load) 32 k oscillator Digital I_{REF} SW1, SW2, SW3, SW4A, SW4B, SW5 in PFM ^{(23),(27)} VDDREF, VPLL, VGEN1, VGEN2, VUSB2, VDAC on in low-power mode ^{(23),(25)} PLL | 370 | 750 | μА | |

Table 8. Current Consumption Summary (24)

Characteristics noted under conditions BP = 3.6 V, -40 °C \leq T_A \leq 85 °C, unless otherwise noted. Typical values at BP = 3.6 V and T_A = 25 °C under nominal conditions, unless otherwise noted.

| Mode | Description | Тур | Max | Unit | Notes |
|------|---|------|------|------|-------|
| ON | Typical use case Digital core RTC logic VCORE module VSRTC CLK32KMCU/CLK32K active (10 pF) 32 k oscillator I_{REF} SW1, SW2, SW3, SW4A, SW4B, SW5 in APS SWBST ^{(23),(26),(27)} VDDREF, VPLL, VGEN1, VGEN2, VUSB2, VDAC on in low-power mode ^{(22),(25)} Digital PLL | 1600 | 3000 | μΑ | |

Notes

22. Equivalent to approx. 30 mW min, 60 mW max

23. Current in RTC Mode is from LICELL=2.5 V; in all other modes from BP = 3.6 V.

24. External loads are not included

25. VUSB2, VGEN2 external pass PNPs

26. SWBST in auto mode

27. SW4A output 2.5 V

6 General Description

The 34709 is the PMIC designed specifically for use with the Freescale i.MX50 and i.MX53 families. As the companion PMIC on several i.MX reference designs, it is a proven solution, which enables a faster time to market with fewer resources.

6.1 Features

Power Generation

- Five buck switching regulators
 - · Two single/dual phase buck regulators
 - · Three single phase buck regulators
 - Up to six independent outputs
 - PFM/Auto pulse skip/PWM operation mode
 - Dynamic voltage scaling
- 5 V boost regulator
 - Support for USB physical layer on i.MX processor (USB PHY)
- Seven LDO regulators
 - · Two with selectable internal or external pass devices
 - · Four with embedded pass devices
 - One with an external PNP device
- One voltage reference for DDR memory with internal PMOS device

Analog to Digital Converter

- Seven general purpose channels
- Eight dedicated channels for monitoring the charger
- Resistive touchscreen interface

Auxiliary Circuits

- General purpose I/Os
- · PWM outputs

Clocking and Oscillators

- · Real time clock
 - · Time and day counters
 - Time of day alarm
- 32.768 kHz crystal oscillator
- Coin cell battery backup
 - · Coin cell charger

Serial Interface

- SPI
- I²C

6.2 Block Diagram

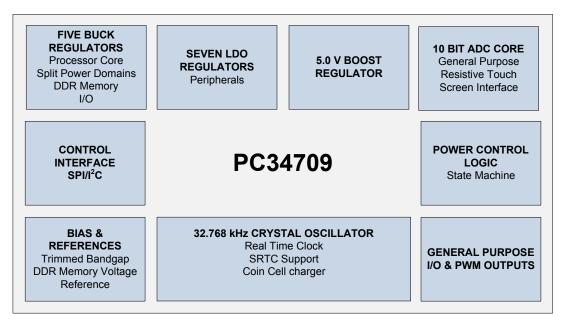

Figure 4. Functional Block Diagram

6.3 Functional Description

The 34709 Power Management Integrated Circuit (PMIC) represents a complete system power solution in a single package. Designed primarily for use with the Freescale i.MX50/53 families. The 34709 integrates five multi-mode buck regulators and seven LDO regulators and one voltage reference for direct supply of the processor core, memory, and peripherals.

The 34709 also integrates a real time clock, coin cell charger, a 16-channel 10-bit ADC, 5.0 V USB boost regulator, two PWM outputs, touch-screen interface, status LED drivers, and four GPIOs.

7 Functional Block Description

7.1 Start-up Requirements

At power-up, switching and linear regulators are sequentially enabled in time slots of 2.0 ms steps, to limit the inrush current after an initial delay of 8.0 ms, in which the core circuitry gets enabled. To ensure a proper power-up sequence, the outputs of the switching regulators that are not enabled, are discharged at the beginning of the Cold start with weak pull-downs on the output. For that same reason, an 8.0 ms delay allows the outputs of the linear regulators to be fully discharged as well, through the built in discharge path. The peak inrush current per event is limited. Any under-voltage detection at BP is masked while the power-up sequencer is running. When the switching regulator is enabled, it will start in PWM mode for 3.0 ms. Then it will switch over to the mode that it is programmed to in the SPI.

The Power-up Mode Select pins PUMSx (x = 1,2,3,4,5) are used to configure the start-up characteristics of the regulators. Supply enabling and output level options are selected by hardwiring the PUMSx pins for the desired configuration. The recommended power-up strategy for end products is to bring up as little of the system as possible at booting, essentially sequestering just the bare essentials to allow processor start-up and software to run. With such a strategy, the start-up transients are controlled at lower levels, and the rest of the system power tree can be brought up by software. This allows optimization of supply ordering, where specific sequences may be required, as well as supply default values. Software code can load up all of the required programmable options, to avoid sneak paths, under/over-voltage issues, start-up surges, etc, without any change in hardware.

The state of the PUMSx pins are latched in before any of the switching or linear regulators are enabled, with the exception of VCORE. PUMSx options and start-up configurations will be robust to a PCUT event, whether occurring during normal operation or during the 8.0 ms of pre-sequencer initialization, i.e., the system will not end up in an unexpected / undesirable consumption state.

Table 9 shows the initial setup for the voltage level of the switching and linear regulators, and whether they get enabled.

34709

7.2 Bias and References Block Description and Application Information

All regulators use the main bandgap as the reference. The main bandgap is bypassed with a capacitor at REFCORE. The bandgap and the rest of the core circuitry is supplied from VCORE. The performance of the regulators is directly dependent on the performance of VCOREDIG and the bandgap. No external DC loading is allowed on VCOREDIG or REFCORE. VCOREDIG is kept powered as long as there is a valid supply and/or coin cell. <u>Table 12</u> shows the main characteristics of the core circuitry.

Table 12. Core Voltages Electrical Specifications

Characteristics noted under conditions BP = 3.6 V, -40 °C \leq T_A \leq 85 °C, unless otherwise noted. Typical values at BP = 3.6 V and T_A = 25 °C under nominal conditions, unless otherwise noted.

Notes

30. 3.0 V < BP < 4.5 V, no external loading on VCOREDIG, VDDLP, VCORE, or REFCORE. Extended operation down to UVDET, but no system malfunction.

31. Powered by VCOREDIG

32. Maximum capacitance on V_{DDLP} should not exceed 1000 pF, including the board capacitance.

7.3 Clocking and Oscillators

7.3.1 Clock Generation

A system clock is generated for internal digital circuitry as well as for external applications utilizing the clock output pins. A crystal oscillator is used for the 32.768 kHz time base and generation of related derivative clocks. If the crystal oscillator is not running (for example, if the crystal is not present), an internal 32 kHz oscillator will be used instead.

Support is also provided for an external Secure Real Time Clock (SRTC), which may be integrated on a companion system processor IC. For media protection in compliance with Digital Rights Management (DRM) system requirements, the CLK32KMCU can be provided as a reference to the SRTC module where tamper protection is implemented.

7.3.1.1 **Clocking Scheme**

The internal 32 kHz oscillator is an integrated backup for the crystal oscillator, and provides a 32.768 kHz nominal frequency at $\pm 60\%$ accuracy, if running. The internal oscillator only runs if a valid supply is available at BP, and would not be used as long as the crystal oscillator is active. In absence of a valid supply at the BP supply node (for instance due to a dead battery), the crystal oscillator continues running supplied from the coin cell battery. All control functions will run off the crystal derived frequency. occasionally referred to as "32 kHz" for brevity's sake.

During the switchover between the two clock sources (such as when the crystal oscillator is starting up), the output clock is maintained at a stable active low or high phase of the internal 32 kHz clock to avoid any clocking glitches. If the XLTAL clock source suddenly disappears during operation, the IC will revert back to the internal clock source. Given the unpredictable nature of the event and the start-up times involved, the clock may be absent long enough for the application to shut down during this transition, such as a sag in the regulator output voltage or absence of a signal on the clock output pins.

A status bit, CLKS, is available to indicate to the processor which clock is currently selected: CLKS=0 when the internal RC is used and CLKS=1 if the crystal source is used. The CLKI interrupt bit will be set whenever a change in the clock source occurs, and an interrupt will be generated if the corresponding CLKM mask bit is cleared.

7.3.1.2 **Oscillator Specifications**

The crystal oscillator has been optimized for use in conjunction with the Micro Crystal CC7V-T1A32.768 kHz-9.0 pF-30 ppm or equivalent (such as Micro Crystal CC5V-T1A or Epson FC135) and is capable of handling its parametric variations.

The electrical characteristics of the 32 kHz Crystal oscillator are given in the following table, taking into account the crystal characteristics noted above. The oscillator accuracy depends largely on the temperature characteristics of the used crystal. Application circuits can be optimized for required accuracy by adapting the external crystal oscillator network (via component accuracy and/or tuning). Additionally, a clock calibration system is provided to adjust the 32,768 cycle counter that generates the 1.0 Hz timer and RTC registers; see SRTC Support for more detail.

Table 13. Oscillator and Clock Main Electrical Specifications

Characteristics noted under conditions BP = 3.6 V, -40 °C \leq T_A \leq 85 °C, unless otherwise noted. Typical values at BP = 3.6 V and $T_A = 25$ °C under nominal conditions, unless otherwise noted.

| Symbol | Characteristic | | Тур | Max | Unit | Notes |

7.3.2 SRTC Support

When configured for DRM mode (SPI bit DRM = 1), the CLK32KMCU driver will be kept enabled through all operational states to ensure that the SRTC module always has its reference clock. If DRM = 0, the CLK32KMCU driver will not be maintained in the Off state.

It is also necessary to provide a means for the processor to do an RTC initiated wake-up of the system if it has been programmed for such capability. This can be accomplished by connecting an open-drain NMOS driver to the PWRON pin of the 34709 PMIC, so that it is in effect, a parallel path for the power key. The 34709 PMIC will not be able to discern the turn on event from a normal power key initiated turn on, but the processor should have the knowledge, since the RTC initiated turn on is generated locally.

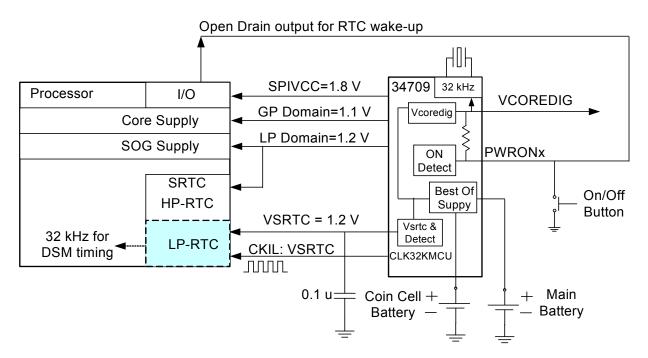

Figure 5. SRTC Block Diagram

7.3.2.1 VSRTC

The VSRTC regulator provides the CLK32KMCU output level. Additionally, it is used to bias the Low-power SRTC domain of the SRTC module integrated on certain FSL processors. The VSRTC regulator is enabled as soon as the RTCPORB is detected. The VSRTC cannot be disabled.

Depending on the configuration of the PUMS[4:0] pins, the VSRTC voltage will be set to 1.3 or 1.2 V. With PUMS[4:0] = (0110, 0111, 1000, or 1001) VSRTC will be set to 1.3 V in on mode (on, on standby and on standby low-power modes). In off and coin cell modes the VSRTC voltage will drop to 1.2 V with the PUMS[4:0] = (0110, 0111, 1000, or 1001). With PUMS[4:0] = (0110, 0111, 1000, or 1001), VSRTC will be set to 1.2 V for all modes (on, on standby, on standby low-power mode, off, and coin cell).

Table 14. VSRTC Electrical Specifications

Characteristics noted under conditions BP = 3.6 V, -40 °C \leq T_A \leq 85 °C, unless otherwise noted. Typical values at BP = 3.6 V and T_A = 25 °C under nominal conditions, unless otherwise noted.

| VSRTC - AC | TIVE MODE - DC (CONTINUED) | | | | | |
| V _{SRTC} | Output Voltage • V _{SRTCINMIN} < V _{STRCIN} < V _{SRTCINMAX} • I _{SRTCMIN} < I _{SRTC} < I _{SRTCMAX} • PUMS[4:0] ≠ (0110, 0111, 1000, 1001) • On, Standby, and Standby LPM modes | 1.15 | 1.2 | 1.25 | v | |
| V _{SRTC} | Output Voltage • V _{SRTCINMIN} < V _{STRCIN} < V _{SRTCINMAX} • I _{SRTCMIN} < I _{SRTC} < I _{SRTCMAX} • PUMS[4:0] = (0110, 0111, 1000, 1001) • On, Standby, and Standby LPM modes | 1.25 | 1.3 | 1.35 | v | |
| I _{SRTCQ} | Active Mode Quiescent Current • V _{SRTCINMIN} < V _{STRCIN} < V _{SRTCINMAX} • I _{SRTC} = 0 | - | 0.8 | - | μΑ | |

7.3.2.2 Real Time Clock

A Real Time Clock (RTC) is provided with time and day counters as well as an alarm function. The RTC utilizes the 32.768 kHz crystal oscillator for the time base and is powered by the coin cell backup supply when BP has dropped below operational range. In configurations where the SRTC is used, the RTC can be disabled to conserve current drain by setting the RTCDIS bit to a 1 (defaults on at power up).

Time and Day Counters

The 32.768 kHz clock is divided into a 1.0 Hz time tick which drives a 17-bit Time Of Day (TOD) counter. The TOD counter counts the seconds during a 24 hour period from 0 to 86,399 and will then roll over to 0. When the roll over occurs, it increments the 15-bit DAY counter. The DAY counter can count up to 32767 days. The 1.0 Hz time tick can be used to generate a 1HZI interrupt if unmasked.

Time Of Day Alarm

A Time Of Day Alarm (TODA) function can be used to turn on the application and alert the processor. If the application is already on, the processor will be interrupted. The TODA and DAYA registers are used to set the alarm time. When the TOD counter is equal to the value in TODA and the DAY counter is equal to the value in DAYA, the TODAI interrupt will be generated.

Timer Reset

As long as the supply at BP is valid, the real time clock will be supplied from VCOREDIG. If BP is not valid, the real time clock can be backed up from a coin cell via the LICELL pin. When the VSRTC voltage drops to the range of 0.9 to 0.8 V, the RTCPORB reset signal is generated and the contents of the RTC will be reset. Additional registers backed up by coin cell will also reset with RTCPORB. To inform the processor that the contents of the RTC are no longer valid due to the reset, a timer reset interrupt function is implemented with the RTCRSTI bit.

RTC Timer Calibration

A clock calibration system is provided to adjust the 32,768 cycle counter that generates the 1.0 Hz timer for RTC timing registers. The general implementation relies on the system processor to measure the 32.768 kHz crystal oscillator against a higher frequency and more accurate system clock, such as a TCXO. If the RTC timer needs a correction, a 5-bit 2's complement calibration word can be sent via the SPI, to compensate the RTC for inaccuracy in its reference oscillator.

| Code in RTCCAL[4:0] | Correction in Counts per 32768 | Relative correction in ppm |
|---------------------|--------------------------------|----------------------------|
| 01111 | +15 | +458 |
| 00011 | +3 | +92 |
| 00001 | +1 | +31 |
| 00000 | 0 | 0 |
| 11111 | -1 | -31 |
| 11101 | -3 | -92 |
| 10001 | -15 | -458 |
| 10000 | -16 | -488 |

Table 15. RTC calibration Settings

The available correction range should be sufficient to ensure drift accuracy in compliance with standards for DRM time keeping. Note that the 32.768 kHz oscillator is not affected by RTCCAL settings; calibration is only applied to the RTC time base counter. Therefore, the frequency at the clock output CLK32K is not affected.

The RTC system calibration is enabled by programming the RTCCALMODE[1:0] for desired behavior by operational mode.

| Table 16. | RTC | Calibration | Enabling |
|-----------|-----|-------------|----------|
|-----------|-----|-------------|----------|

| RTCCALMODE | Function |
|------------|--|
| 00 | RTC Calibration disabled (default) |
| 01 | RTC Calibration enabled in all modes except coin cell only |
| 10 | Reserved for future use. Do not use. |
| 11 | RTC Calibration enabled in all modes |

The RTC Calibration circuitry can be automatically disabled when main battery contact is lost or if it is so deeply discharged that RTC power draw is switched to the coin cell (configured with RTCCALMODE=01).

Because of the low RTC consumption, RTC accuracy can be maintained through long periods of the application being shut down, even after the main battery has discharged. However, it is noted that the calibration can only be as good as the RTCCAL data

that has been provided, so occasional refreshing is recommended to ensure that any drift influencing environmental factors have not skewed the clock beyond desired tolerances.

7.3.3 Coin Cell Battery Backup

The LICELL pin provides a connection for a coin cell backup battery or supercap. If the main battery is deeply discharged, removed, or contact-bounced (i.e., during a power cut), the RTC system and coin cell maintained logic will switch over to the LICELL for backup power. This switch over occurs for a BP below 1.8 V threshold with LICELL greater than BP. A small capacitor should be placed from LICELL to ground under all circumstances.

Upon initial insertion of the coin cell, it is not immediately connected to the on chip circuitry. The cell gets connected when the IC powers on, or after enabling the coin cell charger when the IC was already on.

The coin cell charger circuit will function as a current-limited voltage source, resulting in the CC/CV taper characteristic typically used for rechargeable Lithium-Ion batteries. The coin cell charger is enabled via the COINCHEN bit. The coin cell voltage is programmable through the VCOIN[2:0] bits. The coin cell charger voltage is programmable in the ON state where the charge current is fixed at ICOINHI.

If COINCHEN=1 when the system goes into an Off or User Off state, the coin cell charger will continue to charge to the predefined voltage setting, but at a lower maximum current ICOINLO. This compensates for self discharge of the coin cell and ensures that if/when the main cell gets depleted, that the coin cell will be topped off for maximum RTC retention. The coin cell charging will be stopped for the BP below UVDET. The bit COINCHEN itself is only cleared when an RTCPORB occurs.

| VCOIN[2:0] | Output Voltage |
|------------|----------------|
| 000 | 2.50 |
| 001 | 2.70 |
| 010 | 2.80 |
| 011 | 2.90 |
| 100 | 3.00 |
| 101 | 3.10 |
| 110 | 3.20 |
| 111 | 3.30 |

Table 17. Coin Cell Voltage Specifications

Table 18. Coin Cell Electrical Specifications

Characteristics noted under conditions BP = 3.6 V, -40 °C \leq T_A \leq 85 °C, unless otherwise noted. Typical values at BP = 3.6 V and T_A = 25 °C under nominal conditions, unless otherwise noted.

| Symbol | Characteristic | | Тур | Мах | Unit | Notes |

| | LICELL Bypass Capacitor as coin cell replacement | - | 4.7 | - | μF | |

7.4 Interrupt Management

7.4.1 Control

The system is informed about important events, based on interrupts. Unmasked interrupt events are signaled to the processor by driving the INT pin high; this is true whether the communication interface is configured for SPI or I²C.

Each interrupt is latched so that even if the interrupt source becomes inactive, the interrupt will remain set until cleared. Each interrupt can be cleared by writing a 1 to the appropriate bit in the Interrupt Status register, which will also cause the interrupt line to go low. If a new interrupt occurs while the processor clears an existing interrupt bit, the interrupt line will remain high.

Each interrupt can be masked by setting the corresponding mask bit to a 1. As a result, when a masked interrupt bit goes high, the interrupt line will not go high. A masked interrupt can still be read from the Interrupt Status register. This gives the processor the option of polling for status from the IC. The IC powers up with all interrupts masked, so the processor must initially poll the device to determine if any interrupts are active. Alternatively, the processor can unmask the interrupt bits of interest. If a masked interrupt bit was already high, the interrupt line will go high after unmasking.

The sense registers contain status and input sense bits, so the system processor can poll the current state of interrupt sources. They are read only, and not latched or clearable.

Interrupts generated by external events are debounced. Therefore, the event needs to be stable throughout the debounce period before an interrupt is generated. Nominal debounce periods for each event are documented in the INT summary table following later in this section. Due to the asynchronous nature of the debounce timer, the effective debounce time can vary slightly.

7.4.2 Interrupt Bit Summary

<u>Table 19</u> summarizes all interrupt, mask, and sense bits associated with INT control. For more detailed behavioral descriptions, refer to the related chapters.

| Interrupt | Mask | Sense | Purpose | Trigger | Debounce Time |
|-----------|-----------|---------|--|---------|---------------------------|
| ADCDONEI | ADCDONEM | - | ADC has finished requested conversions | L2H | 0.0 |
| TSDONEI | TSDONEM | - | Touch screen has finished conversion | L2H | 0.0 |
| TSPENDET | TSPENDETM | - | Touch screen pen detect | Dual | 1.0 ms |
| LOWBATT | LOWBATTM | - | Low battery detect Sense is 1 if below LOWBAT threshold | H2L | Programmable VBATTDB |
| SCPI | SCPM | - | Regulator short-circuit protection tripped | L2H | min. 4.0 ms max 8.0 ms |
| 1HZI | 1HZM | - | 1.0 Hz time tick | L2H | 0.0 |
| TODAI | TODAM | - | Time of day alarm | L2H | 0.0 |
| PWRON1I | PWRON1M | PWRON1S | Power on button 1 event | H2L | 30 ms ⁽³³⁾ |
| FWRONII | FWRONIW | FWRONIS | Sense is 1 if PWRON1 is high. | L2H | 30 ms |
| PWRON2I | PWRON2M | PWRON2S | Power on button 2 event | H2L | 30 ms ⁽³³⁾ |
| PWRONZI | PWRONZW | PWRON25 | Sense is 1 if PWRON2 is high. | L2H | 30 ms |
| SYSRSTI | SYSRSTM | - | System reset through PWRONx pins | L2H | 0.0 |
| WDIRESETI | WDIRESETM | - | WDI silent system restart | L2H | 0.0 |
| PCI | PCM | - | Power cut event | L2H | 0.0 |
| WARMI | WARMM | - | Warm Start event | L2H | 0.0 |
| MEMHLDI | MEMHLDM | - | Memory Hold event | L2H | 0.0 |

Table 19. Interrupt, Mask and Sense Bits

Table 19. Interrupt, Mask and Sense Bits

| Interrupt | Mask | Sense | Purpose | Trigger | Debounce Time |
|-----------|-----------|-----------|--|--------------|------------------|
| CLKI | CLKM | CLKS | 32 kHz clock source change Sense is 1 if source is XTAL | Dual | 0.0 |
| RTCRSTI | RTCRSTM | - | RTC reset has occurred | L2H | 0.0 |
| THERM110 | THERM110M | THERM110S | Thermal 110 °C threshold Sense is 1 if above threshold | Dual | 30 ms |
| THERM120 | THERM120M | THERM120S | Thermal 120 °C threshold Sense is 1 if above threshold | Dual | 30 ms |
| THERM125 | THERM125M | THERM125S | Thermal 125 °C threshold Sense is 1 if above threshold | Dual | 30 ms |

| GPIOLVxI | GPIOLVxM | GPIOLVxS | General Purpose input interrupt | Programmable | Programmable |

Notes

33. Debounce timing for the falling edge can be extended with PWRONxDBNC[1:0]; refer to Serial Interfaces for details.

7.5 Power Generation

The 34709 PMIC provides reference and supply voltages for the application processor as well as peripheral device.

Six buck (step down) converters and one boost (step up) converters are included. One of the buck regulators can be configured in multiphase, single phase mode, or operate as separate independent outputs (in this case, there are six buck converters). The buck converters provide the supply to processor cores and to other low-voltage circuits such as IO and memory. Dynamic voltage scaling is provided to allow controlled supply rail adjustments for the processor cores and/or other circuitry. The boost converter supplies the VUSB regulator for the USB PHY on the processor. The VUSB regulator is powered from the boost to ensure sufficient headroom for the LDO through the normal discharge range of the main battery.

Linear regulators are directly supplied from the battery or from the switching regulator, and include supplies for IO and peripherals, such as audio, camera, Bluetooth, Wireless LAN, etc. Naming conventions are suggestive of typical or possible use case applications, but the switching and linear regulators may be utilized for other system power requirements within the guidelines of specified capabilities. Four general purpose I/Os are available, which can be configured as inputs/outputs. As inputs they can be configured as interrupts.

7.5.1 Power Tree

Refer to the representative tables and text specifying each supply for information on performance metrics and operating ranges.

Table 20 summarizes the available power supplies.

| Supply | Purpose (typical application) | Output Voltage (in V) | Load Capability (in mA) | |
|---------|---|-------------------------------------|-------------------------|--|
| SW1 | Buck regulator for processor VDDGP domain | 0.650 – 1.4375 | | |
| SW2 | Buck regulator for processor VCC domain | 0.650 – 1.4375 | 1000 | |
| SW3 | Buck regulator for processor VDD domain and peripherals | 0.650 - 1.425 | 500 | |
| SW4A | Buck regulator for DDR memory and peripherals | 1.200 – 1.85: 2.5/3.15 | 500 | |
| SW4B | Buck regulator for DDR memory and peripherals | 1.200 – 1.85: 2.5/3.15 | 500 | |
| SW5 | Buck regulator for I/O domain | 1.200 – 1.85 | 1000 | |
| SWBST | Boost regulator for USB PHY support | 5.00/5.05/5.10/5.15 | 380 | |
| VSRTC | Secure Real Time Clock supply | 1.2 | 0.05 | |
| VPLL | Quiet Analog supply | 1.2/1.25/1.5/1.8 | 50 | |
| VREFDDR | DDR Ref supply | 0.6 - 0.9 | 10 | |
| VDAC | TV DAC supply, external PNP | 2.5/2.6/2.7/2.775 | 250 | |
| VUSB2 | VUSB/peripherals supply, internal PMOS | 2.5/2.6/2.75/3.0 | 65 | |
| | VUSB/peripherals external PNP | 2.5/2.6/2.75/3.0 | 350 | |
| VGEN1 | General peripherals supply #1 | 1.2/1.25/1.3/1.35/1.4/1.45/1.5/1.55 | 250 | |
| VGEN2 | General peripherals supply #2, internal PMOS | 2.5/2.7/2.8/2.9/3.0/3.1/3.15/3.3 | 50 | |
| | General peripherals supply #2, external PNP | 2.5/2.7/2.8/2.9/3.0/3.1/3.15/3.3 | 250 | |
| VUSB | USB Transceiver supply | 3.3 | 100 | |

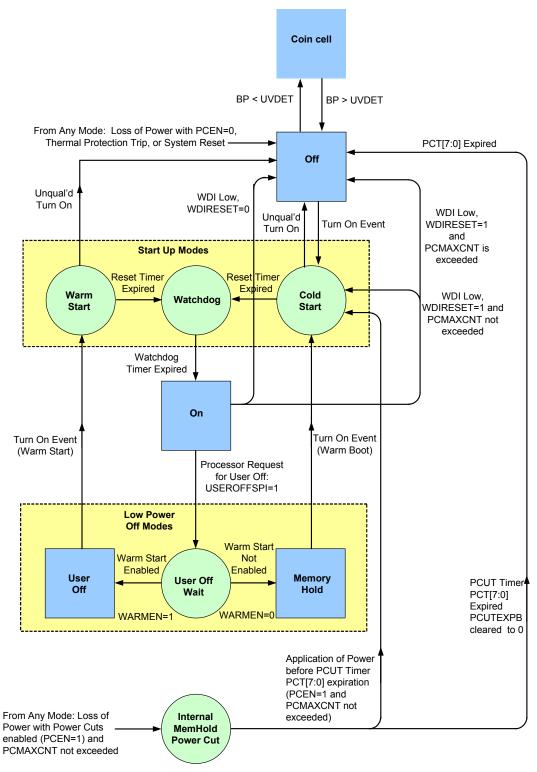

Table 20. Power Tree Summary

7.5.2 Modes of Operation

The 34709 PMIC is fully programmable via the SPI interface and associated register map. Additional communication is provided by direct logic interfacing, including interrupt, watchdog, and reset. Default start-up of the device is selectable by hardwiring the Power-up Mode Select (PUMS) pins.

Power cycling of the application is driven by the 34709 PMIC. It has the interfaces for the power buttons and dedicated signaling interfacing with the processor. It also ensures the supply of the Real Time Clock (RTC), critical internal logic, and other circuits from the coin cell, in case of brief interruptions from the main battery. A charger for the coin cell is included to ensure that it is kept topped off until needed.

The 34709 PMIC provides the timekeeping, based on an integrated low-power oscillator running with a standard watch crystal. This oscillator is used for internal clocking, the control logic, and as a reference for the Regulator PLL. The timekeeping includes time of day, calendar, and alarm, and is backed up by coin cell. The clock is driven to the processor for reference and deep sleep mode clocking.

The following are text descriptions of the power states of the system for additional details of the state machine to complement the drawing in <u>Figure 6</u>. Note that the SPI control is only possible in the Watchdog, On and User Off Wait states, and that the interrupt line INT is kept low in all states except for Watchdog and On.

7.5.2.1 Coin Cell

The RTC module is powered from either the battery or the coin cell, due to insufficient voltage at BP, and the IC is not in a Power Cut. No Turn On event is accepted in the Coin Cell state. Transition out (to the Off state) requires BP restoration with a threshold above UVDET. RESETB, and RESETBMCU are held low in this mode.

The RTC module remains active (32 kHz oscillator + RTC timers), along with BP level detection to qualify exit to the Off state. VCOREDIG is off and the VDDLP regulator is on, the rest of the system is put into its lowest power configuration.

If the coin cell is depleted (VSTRC drops to 0.9 V to 0.8 V while in the Coin Cell state), a complete system reset will occur. At next power application / Turn On event, the system will start-up reinitialized with all SPI bits including those that reset on RTCPORB restored to their default states.

7.5.2.2 Off (with good battery)

If the supply VALWAYS is above the UVDET threshold, only the IC core circuitry at VCOREDIG and the RTC module are powered, all other supplies are inactive. To exit the Off mode, a valid turn on event is required. No specific timer is running in this mode. RESETB and RESETBMCU are held low in this mode.

If BP is below the UVDET threshold, no turn on events are accepted. If a valid coin cell is present, the core gets powered from LICELL. The only active circuitry is the RTC module and the detection VCORE module powering VCOREDIG at 1.5 V.

To exit the OFF mode, a valid turn ON event is required.

7.5.2.3 Cold Start

Cold Start is entered upon a Turn On event from Off, Warm Boot, successful PCUT, or a Silent System Restart. The first 8.0 ms is used for initialization which includes bias generation, PUMSx configuration latching, and qualification of the input supply level BP. The switching and linear regulators are then powered up sequentially to limit the inrush current; see the Power-up section for sequencing and default level details. The reset signals RESETB and RESETBMCU are kept low. The Reset timer starts running when entering Cold Start. The Cold Start state is exited for the Watchdog state and both RESETB and RESETBMCU become high (open-drain output with external pull-ups) when the reset timer is expired. The input control pins WDI, and STANDBY are ignored.

7.5.2.4 Watchdog

The system is fully powered and under SPI control. RESETB and RESETBMCU are high. The Watchdog timer starts running when entering the Watchdog state. When expired, the system transitions to the On state, where WDI will be checked and monitored. The input control pins WDI and STANDBY are ignored while in the Watchdog state.

7.5.2.5 On Mode

The system is fully powered and under SPI control. RESETB and RESETBMCU are high. The WDI pin must be high to stay in this mode. The WDI IO supply voltage is referenced to SPIVCC (normally connected to SW5 = 1.8 V); SPIVCC must therefore remain enabled to allow for proper WDI detection. If WDI goes low, the system will transition to the Off state or Cold Start (depending on the configuration; refer to the section on Silent System Restart with WDI Event for details).

7.5.2.6 User Off Wait

The system is fully powered and under SPI control. The WDI pin no longer has control over the part. The Wait mode is entered by a processor request for user off by setting the USEROFFSPI bit high. This is normally initiated by the end user via the power key; upon receiving the corresponding interrupt, the system will determine if the product has been configured for User Off or Memory Hold states (both of which first require passing through User Off Wait) or just transition to Off.

The Wait timer starts running when entering User Off Wait mode. This leaves the processor time to suspend or terminate its tasks. When expired, the Wait mode is exited for User Off mode or Memory Hold mode depending on warm starts being enabled or not via the WARMEN bit. The USEROFFSPI bit is being reset at this point by RESETB going low.

7.5.2.7 Memory Hold and User Off (Low-power Off states)

As noted in the User Off Wait description, the system is directed into low-power Off states based on a SPI command in response to an intentional turn off by the end user. The only exit then will be a turn on event. To an end user, the Memory Hold and User Off states look like the product has been shut down completely. However, a faster start-up is facilitated by maintaining external memory in self-refresh mode (Memory Hold and User Off mode) as well as powering portions of the processor core for state retention (User Off only). The Switching regulator mode control bits allow selective powering of the buck regulators for optimizing the supply behavior in the low-power Off modes. Linear regulators and most functional blocks are disabled (the RTC module, SPI bits resetting with RTCPORB, and Turn On event detection are maintained).

By way of example, the following descriptions assume the typical use case where SW1 supplies the processor core(s), SW2 is applied to the processor's VCC domain, SW3 supplies the processors internal memory/peripherals, SW4 supplies the external memory, and SW5 supplies the I/O rail. The buck regulators are intended for direct connection to the aforementioned loads.

7.5.2.8 Memory Hold

RESETB and RESETBMCU are low, and both CLK32K and CLK32KMCU are disabled (CLK32KMCU active if DRM is set). To ensure that SW1, SW2, SW3, and SW5 shut off in Memory Hold, appropriate mode settings should be used such as SW1MHMODE, = SW2MHMODE, = SW3MHMODE, = SW5MHMODE set to = 0 (refer to the mode control description later in this section). Since SW4 should be powered in PFM mode, SW4MHMODE could be set to 1.

Upon a Turn On event, the Cold Start state is entered, the default power-up values are loaded, and the MEMHLDI interrupt bit is set. A Cold Start out of the Memory Hold state will result in shorter boot times compared to starting out of the Off state, since software does not have to be loaded and expanded from flash. The start-up out of Memory Hold is also referred to as Warm Boot. No specific timer is running in this mode.

Buck regulators that are configured to stay on in MEMHOLD mode by their SWxMHMODE settings will not be turned off when coming out of MEMHOLD and entering a Warm Boot. The switching regulators will be reconfigured for their default settings as selected by the PUMSx pins in the normal time slot that would affect them.

7.5.2.9 User Off

RESETB is low and RESETBMCU is kept high. The 32 kHz peripheral clock driver CLK32K is disabled; CLK32KMCU (connected to the processor's CKIL input) is maintained in this mode if the CLK32KMCUEN and USEROFFCLK bits are both set, or if DRM is set.

The memory domain is held up by setting SW4UOMODE = 1. Similarly, the SW1 and/or SW2 and/or SW3 supply domains can be configured for SWxUOMODE=1 to keep them powered through the User Off event. If one of the switching regulators can be shut down on in User Off, its mode bits would typically be set to 0.

Since power is maintained for the core (which is put into its lowest power state), and since MCU RESETBMCU does not trip, the processor's state may be quickly recovered when exiting USEROFF upon a turn on event. The CLK32KMCU clock can be used for very low frequency / low-power idling of the core(s), minimizing battery drain, while allowing a rapid recovery from where the system left off before the USEROFF command.

Upon a turn on event, Warm Start state is entered, and the default power-up values are loaded. A Warm Start out of User Off will result in an almost instantaneous start-up of the system, since the internal states of the processor were preserved along with external memory. No specific timer is running in this mode.

7.5.2.10 Warm Start

Entered upon a Turn On event from User Off. The first 8.0 ms is used for initialization, which includes bias generation, PUMSx latching, and qualification of the input supply level BP. The switching and linear regulators are then powered up sequentially to limit the inrush current; see Start-up Requirements for sequencing and default level details. If SW1, SW2, SW3, SW4, and/or SW5, were configured to stay on in User Off mode by their SWxUOMODE settings, they will not be turned off when coming out of User Off and entering a Warm Start. The buck regulators will be reconfigured for their default settings as selected by the PUMSx pins in the respective time slot defined in the sequencer selection.

RESETB is kept low and RESETBMCU is kept high. CLK32KMCU is kept active if CLK32KMCU was set. The reset timer starts running when entering Warm Start. When expired, the Warm Start state is exited for the Watchdog state, a WARMI interrupt is generated, and RESETB will go high.

7.5.2.11 Internal MemHold Power Cut

As described in the Power Cut Description, a momentary power interruption will put the system into the Internal MemHold Power Cut state if PCUTs are enabled. The backup coin cell will now supply the 34709 core along with the 32 k crystal oscillator, the RTC system, and coin cell backed up registers. All regulators will be shut down to preserve the coin cell and RTC as long as possible.

Both RESETB and RESETBMCU are tripped, bringing the entire system down along with the supplies and external clock drivers, so the only recovery out of a Power Cut state is to reestablish power and initiate a Cold Start.

If the PCT timer expires before power is re-established, the system transitions to the Off state and awaits a sufficient supply recovery.

7.5.3 Power Control Logic

7.5.3.1 Power Cut Description

When the BP drops below the UVDET threshold, due to battery bounce or battery removal, the Internal MemHold Power Cut mode is entered and a Power Cut (PCUT) timer starts running. The backup coin cell will now supply the RTC as well as the on chip memory registers and some other power control related bits. All other supplies will be disabled.

The maximum duration of a power cut is determined by the PCUT timer PCT [7:0] preset via the SPI. When a PCUT occurs, the PCUT timer will be started. The contents of PCT [7:0] does not reflect the actual count down value, but will keep the programmed value, and therefore does not have to be reprogrammed after each power cut.

If power is not re-established above the 3.0 V threshold before the PCUT timer expires, the state machine transitions to the Off mode at expiration of the counter, and clears the PCUTEXB bit by setting it to 0. This transition is referred to as an "unsuccessful" PCUT. In addition the PMIC will bring the SDWNB pin low for one 32 kHz clock cycle before powering down.

Upon re-application of power before expiration (a "successful PCUT", defined as BP first rising above the UVDET threshold and then battery above the 3.0 V threshold before the PCUT timer expires), a Cold Start is engaged after the UVTIMER has expired.

In order to distinguish a non-PCUT initiated Cold Start from a Cold Start after a PCUT, the PCI interrupt should be checked by software. The PCI interrupt is cleared by software or when cycling through the Off state.

Because the PCUT system quickly disables the entire power tree, the battery voltage may recover to a level with the appearance of a valid supply once the battery is unloaded. However, upon a restart of the IC and power sequencer, the surge of current through the battery and trace impedances can once again cause the BP node to droop below UVDET. This chain of cyclic power down / power-up sequences is referred to as "ambulance mode", and the power control system includes strategies to minimize the chance of a product falling into and getting stuck in ambulance mode.

First, the successful recovery out of a PCUT requires the BP node to rise above LOBATT threshold, providing hysteretic margin from the LOBATT (H to L) threshold. Secondly, the number of times the PCUT mode is entered is counted with the counter PCCOUNT [3:0], and the allowed count is limited to PCMAXCNT [3:0] set through the SPI. When the contents of both become equal, then the next PCUT will not be supported and the system will go to Off mode, after the PCUT time expires.

After a successful power-up after a PCUT (i.e., valid power is reestablished, the system comes out of reset, and the processor reassumes control), software should clear the PCCOUNT [3:0] counter. Counting of PCUT events is enabled via the PCCOUNTEN bit. This mode is only supported if the power cut mode feature is enabled by setting the PCEN bit. When not enabled, then in case of a power failure, the state machine will transition to the Off state. SPI control is not possible during a PCUT event and the interrupt line is kept low. SPI configuration for PCUT support should also include setting the PCUTEXPB = 1 (See Silent Restart from PCUT Event).

7.5.3.2 Silent Restart from PCUT Event

If a short duration power cut event occurs (such as from a battery bounce, for example), it may be desirable to perform a silent restart, so the system is reinitialized without alerting the user. This can be facilitated by setting the PCUTEXPB bit to "1" at booting or after a Cold Start. This bit resets on RTCPORB, therefore any subsequent Cold Start can first check the status of PCUTEXPB and the PCI bit. The PCUTEXPB is cleared to "0" when transitioning from PCUT to Off. If there was a PCUT interrupt and PCUTEXPB is still "1", then the state machine has not transitioned through Off, which confirms that the PCT timer has not expired during the PCUT event (i.e., a successful power cut). In this case, a silent restart may be appropriate.

If PCUTEXPB is found to be "0" after the Cold Start where PCI is found to be "1", then it is inferred that the PCT timer has expired before power was reestablished, flagging an unsuccessful power cut or first power-up, so the start-up user greeting may be desirable for playback.

7.5.3.3 Silent System Restart with WDI Event

A mechanism is provided for recovery if the system software somehow gets into an abnormal state which requires a system reset, but it is desired to make the reset a silent event so as to happen without end user awareness. The default response to WDI going low is for the state machine to transition to the Off state (when WDIRESET = 0). However, if WDIRESET = 1, the state machine will go to Cold Start without passing through Off mode (i.e., does not generate an OFFB signal).

A WDIRESET event will generate a maskable WDIRESETI interrupt and also increment the PCCOUNT counter. This function is unrelated to PCUTs, but it shares the PCUT counter so that the number of silent system restarts can be limited by the programmable PCMAXCNT counter.

When PCUT support is used, the software should set the PCUTEXPB bit to "1". Since this bit resets with RTCPORB, it will not be reset to "0" if a WDI falls and the state machine goes straight to the Cold Start state. Therefore, upon a restart, software can discern a silent system restart if there is a WDIRESETI interrupt and PCUTEXPB = 1. The application may then determine that an inconspicuous restart without fanfare may be more appropriate than launching into the welcoming routine.

A PCUT event does not trip the WDIRESETI bit.

Note that the system response to WDI is gated by the Watchdog timer—once the timer has expired, then the system will respond as programmed by WDIRESET and described above.

7.5.3.4 Turn On Events

When in Off mode, the circuit can be powered on via a Turn On event. The Turn On events are listed by the following. To indicate to the processor what event caused the system to power on, an interrupt bit is associated with each of the Turn On events. Masking the interrupts related to the turn on events will not prevent the part to turn on except for the time of day alarm. If the part was already on at the time of the turn on event, the interrupt is still generated.

 Power Button Press: PWRON1, or PWRON2 pulled low with corresponding interrupts and sense bits PWRON11 or PWRON2I, and PWRON1S or PWRON2S. A power on/off button is connected from PWRONx to ground. The PWRONx can be hardware debounced through a programmable debouncer PWRONxDBNC [1:0] to avoid a response upon a very short (i.e., unintentional) key press. BP should be above UVDET to allow a power-up. The PWRONxI interrupt is generated for both the falling and the rising edge of the PWRONx pin. By default, a 30 ms interrupt debounce is applied to both falling and rising edges. The falling edge debounce timing can be extended with PWRONxDBNC[1:0] as defined in the following table. The PWRONxI interrupt is cleared by software or when cycling through the Off mode.

| Bits | State | Turn On Debounce (ms) | Falling Edge INT Debounce (ms) | Rising Edge INT Debounce (ms) |
|-----------------|-------|--------------------------|-----------------------------------|----------------------------------|
| | 00 | 0.0 | 31.25 | 31.25 |
| PWRONxDBNC[1:0] | 01 | 31.25 | 31.25 | 31.25 |
| FWRONXDBNC[1.0] | 10 | 125 | 125 | 31.25 |
| | 11 | 750 | 750 | 31.25 |

Table 21. PWRONx Hardware Debounce Bit Settings⁽³⁴⁾

Notes

34. The sense bit PWRONxS is not debounced and follows the state of the PWRONx pin.

- Battery Attach: This occurs when BP crosses the 3.0V threshold and the UVDET rising threshold which is equivalent to attaching a charged battery or supply to the product.
- **RTC Alarm:** TOD and DAY become equal to the alarm setting programmed. This allows powering up a product at a preset time. BP should be above 3.0V, and BP should have crossed the UVDET rising threshold and not transitioned below the UVDET falling threshold.
- System Restart: System restart which may occur after a system reset as described earlier in this section. This is an optional
 function, see Turn Off Events. BP should be above 3.0 V and BP should have crossed the UVDET rising threshold and not
 transitioned below the UVDET falling threshold.

Global System Reset: The global reset feature powers down the part, disables the charger, resets the SPI registers to their default value including all the RTCPORB registers (except the DRM bit, and the RTC registers), and then powers back on. To enable a global reset, the GLBRST pin needs to be pulled low for greater than GLBRSTTMR [1:0] seconds and then pulled back high (defaults to 12 s). BP should be above 3.0 V.

| _ | | |
|----------------|--------------|----------|
| Bits | State | Time (s) |
| GLBRSTTMR[1:0] | 00 | Invalid |
| | 01 | 4.0 |
| | 10 | 8.0 |
| | 11 (default) | 12 |

| Table 22. | Global | Reset | Time | Settings |
|-----------|--------|-------|------|----------|
|-----------|--------|-------|------|----------|

7.5.3.5 Turn Off Events

- Power Button Press (via WDI): User shut down of a product is typically done by pressing the power button connected to the PWRONx pin. This will generate an interrupt (PWRONxI), but will not directly power off the part. The product is powered off by the processor's response to this interrupt, which will be to pull WDI low. Pressing the power button is therefore under normal circumstances not considered as a turn off event for the state machine. However, since the button press power down is the most common turn off method for end products, it is described in this section as the product implementation for a WDI initiated Turn Off event. Note that the software can configure a user initiated power down, via a power button press for transition to a Low-power Off mode (Memory Hold or User Off) for a quicker restart than the default transition into the Off state.
- **Power Button System Reset:** A secondary application of the PWRONx pins is the option to generate a system reset. This is recognized as a Turn Off event. By default, the system reset function is disabled but can be enabled by setting the PWRONxRSTEN bits. When enabled, a four second long press on the power button will cause the device to go to the Off mode, and as a result, the entire application will power down. An interrupt SYSRSTI is generated upon the next power-up. Alternatively, the system can be configured to restart automatically by setting the RESTARTEN bit.
- **Thermal Protection:** If the die gets overheated, the thermal protection will power off the part to avoid damage. A Turn On event will not be accepted while the thermal protection is still being tripped. The part will remain in Off mode until cooling sufficiently to accept a Turn On event. There are no specific interrupts related to this other than the warning interrupts.
- **Under-voltage Detection:** When the voltage at BP drops below the under-voltage detection threshold UVDET, the state machine will transition to Off mode if PCUT is not enabled, or if the PCT timer expires when PCUT is enabled. The SDWNB pin is used to notify that the processor that the PMIC is going to immediately shut down. The PMIC will bring the SDWNB pin low for one 32 kHz clock cycle before powering down. This signal will then be brought back high in the power Off state.

7.5.3.6 Timers

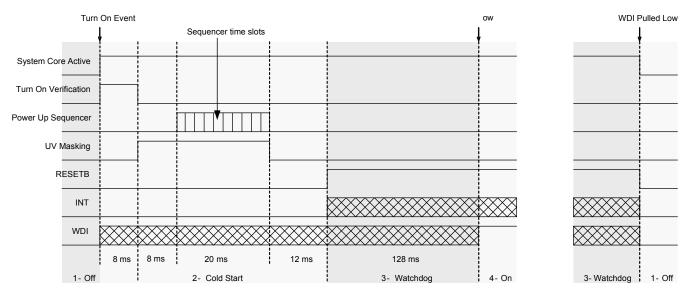

The different timers as used by the state machine are listed by the following. This listing does not include RTC timers for timekeeping. A synchronization error of up to one clock period may occur with respect to the occurrence of an asynchronous event, the duration listed below is therefore the effective minimum time period.

| Timer | Duration | Clock |
|---------------------|--|-----------|
| Under-voltage Timer | 4.0 ms | 32 k/32 |
| Reset Timer | 40 ms | 32 k/32 |
| Watchdog Timer | 128 ms | 32 k/32 |
| Power Cut Timer | Programmable 0 to 8 seconds in 31.25 ms steps | 32 k/1024 |

Table 23. Timer Main Characteristics

7.5.3.6.1 **Timing Diagrams**

A Turn On event timing diagrams shown in Figure 7.

Power up of the system upon a Turn On Event followed by a transition to the On state if WDI is pulled high Turn on Event is based on PWRON being pulled low

... or transition to Off state if WDI remains low

= Indeterminate State

Figure 7. Power-up Timing Diagram

7.5.3.7 **Power Monitoring**

The voltage at BP are monitored by detectors as summarized in Table 24.

| Threshold | Voltage (V) |
|---|-------------|
| Power on | 3.0 |
| Low input supply warning • BP (H to L) ⁽³⁵⁾ | 2.9 |
| UVDET rising ⁽³⁶⁾ | 3.0 |
| UVDT Falling ⁽³⁶⁾ | 2.65 |

Table 24. LOWBATT Detection Thresholds

Notes

35. 50 mV hysteresis is applied.

36. ± 4.0 % tolerance

The UVDET and Power on thresholds are related to the power on/off events as described earlier in this chapter. In order for the IC to power on, BP must rise above the UVDET rising threshold, and the power on threshold (3.0 V) threshold. When the BP node decreases below the 2.9 V threshold, a low input supply warning will be sent to the processor via the LOWBATTI interrupt.

The LOWBATTI detection threshold is debounced by the VBATTDB[2:0] SPI bits shown in Table 25.

| VATTDB[1:0] | Debounce Time (ms) |
|--------------|--------------------|
| 00 | 0.1 |
| 01 | 1.0 |
| 10 | 2.5 |
| 11 (default) | 3.9 |

Table 25. VBATTDB Debounce Times

7.5.3.8 Power Saving

7.5.3.8.1 System Standby

A product may be designed to enter DSM after periods of inactivity, the STANDBY pin is provided for board level control of timing in and out of such deep sleep modes.

When a product is in DSM, it may be able to reduce the overall platform current by lowering the regulator output voltage, changing the operating mode of the switching regulators, or disabling some regulators. This can be obtained by controlling the STANDBY pin. The configuration of the regulators in standby is pre-programmed through the SPI.

A lower power standby mode can be obtained by setting the ON_STBY_LP SPI bit to a one. With the ON_STBY_LP SPI bit set and the STANDBY pin asserted, a lower power standby will be entered. In the on Standby Low-power mode, the switching Regulators should all be programmed into PFM mode, and the LDO's should be configured to Low-power mode when the STANDBY pin is asserted. The PLL is disabled in this mode

Note that the STANDBY pin is programmable for Active High or Active Low polarity, and the decoding of a Standby event will take into account the programmed input polarity associated with each pin. For simplicity, Standby will generally be referred to as active high throughout this document, but as defined in <u>Table 26</u>, active low operation can be accommodated. Finally, since the STANDBY pin activity is driven asynchronously to the system, a finite time is required for the internal logic to qualify and respond to the pin level changes.

| STANDBY (Pin) | STANDBYINV (SPI bit) | STANDBY Control ⁽³⁷⁾ |
|---------------|----------------------|---------------------------------|
| 0 | 0 | 0 |
| 0 | 1 | 1 |
| 1 | 0 | 1 |
| 1 | 1 | 0 |
| | | |

 Table 26. Standby Pin and Polarity Control

Notes

37. STANDBY = 0: System is not in Standby STANDBY = 1: System is in Standby

The state of the STANDBY pin only has influence in On mode, and are therefore it is ignored during start-up and in the Watchdog phase. This allows the system to power-up without concern of the required Standby polarities since software can make adjustments accordingly as soon as it is running.

A command to transition to one of the low-power Off states (User Off or Memory Hold, initiated with USE-ROFFSPI=1) redefines the power tree configuration based on SWxMODE programming, and has priority over Standby (which also influences the power tree configuration).

7.5.3.8.2 Standby Delay

A provision to delay the Standby response is included. This allows the processor and peripherals, some time after a Standby instruction has been received, to terminate processes to facilitate seamless Standby exiting and re-entrance into Normal operating mode.

A programmable delay is provided to hold off the system response to a Standby event. When enabled (STBYDLY = 01, 10, or 11), STBYDLY will delay the STANDBY initiated response for the entire IC until the STBYDLY counter expires.

Note that this delay is applied only when going into Standby, and no delay is applied when coming out of Standby. Also, an allowance should be accounted for synchronization of the asynchronous Standby event and the internal clocking edges (up to a full 32 k cycle of additional delay).

| STBYDLY[1:0] | Function |
|--------------|---------------------------|
| 00 | No Delay |
| 01 | One 32 k period (default) |
| 10 | Two 32 k periods |
| 11 | Three 32 k periods |

Table 27. Delay of STANDBY- Initiated Response

7.5.4 Buck Switching Regulators

Six buck switching regulators are provided with integrated power switches and synchronous rectification. In a typical application, SW1 and SW2 are used for supplying the application processor core power domains. Split power domains allow independent DVS control for processor power optimization, or to support technologies with a mix of device types with different voltage ratings. SW3 is used for powering internal processor memory as well as low-voltage peripheral devices and interfaces which can run at the same voltage level. SW4A/B is used for powering external DDR memory as well as low-voltage peripheral devices and interfaces and interfaces, which can run at the same voltage level. SW5 is used to supply the I/O domain for the system.

The buck regulators are supplied from the system supply BP, which is drawn from the main battery

The switching regulators can operate in different modes depending on the load conditions. These modes can be set through the SPI and include a PFM mode, PWM Pulse Skip, an Automatic Pulse Skipping mode, and a PWM mode.

| Mode | Description |
|-------|---|
| OFF | The regulator is switched off and the output voltage is discharged |
| PFM | The regulator is switched on and set to PFM mode operation. In this mode, the regulator is always running in PFM mode. Useful at light loads for optimized efficiency. |
| APS | The regulator is switched on and set to Automatic Pulse Skipping. In this mode the regulator moves automatically between pulse skipping and full PWM mode depending on load conditions. |
| PWM | The regulator is switched on and set to PWM mode. In this mode the regulator is always in full PWM mode operation regardless of load conditions. |
| PWMPS | The regulator is alternating between pulse skipping and PWM modes, depending on the load conditions. |

Table 28. Buck Operating Modes

Buck modes of operation are programmable for explicitly defined or load-dependent control.

When initially activated, regulators outputs will apply controlled stepping to the programmed value. The soft start feature limits the inrush current at start-up. During soft start, the regulator will be forced to PWM mode for 3.0 ms and then default to the APS mode A built in current limiter ensures that during normal operation the maximum current through the coil is not exceeded.

Point of Load feedback is intended for minimizing errors due to board level IR drops.

7.5.4.1 General Control

Operational modes of the Buck regulators can be controlled by direct SPI programming, altered by the state of the STANDBY pin, by direct state machine influence (i.e., entering Off or low-power Off states, for example), or by load current magnitude when so configured (Auto Pulse skip mode). Available modes include PWM with No Pulse Skipping (PWM), PWM with Pulse Skipping (PWMPS), Pulse Frequency Mode (PFM), Automatic Pulse Skip (APS), and Off. The transition between the two modes PWMPS and PWM can occur automatically, based on the load current (auto pulse skip mode). For light loading, the regulators should be put into PFM mode to optimize efficiency.

SW1A/B, SW2, SW3, SW4A/B, and SW5, can be configured for mode switching with STANDBY or autonomously, based on load current Auto pulse skip mode. Additionally, provisions are made for maintaining PFM operation in User off and Memhold modes,

to support state retention for faster start-up from the Low-power Off modes for Warm Start or Warm Boot. SWxMODE[3:0] bits will be reset to their default values defined by PUMSx settings by the start-up sequencer.

Table 29 summarizes the Buck regulators programmability for Normal and Standby modes.

| SWxMODE[3:0] | Normal Mode | Standby Mode |
|--------------|-------------|--------------|
| 0000 | Off | Off |
| 0001 | PWM | Off |
| 0010 | PWMPS | Off |
| 0011 | PFM | Off |
| 0100 | APS | Off |
| 0101 | PWM | PWM |
| 0110 | PWM | APS |
| 0111 | Off | Off |
| 1000 | APS | APS |
| 1001 | PWM | PWMPS |
| 1010 | PWMPS | PWMPS |
| 1011 | PWMPS | APS |
| 1100 | APS | PFM |
| 1101 | PWM | PFM |
| 1110 | PWMPS | PFM |
| 1111 | PFM | PFM |

Table 29. Switching regulator Mode Control for Normal and Standby Operation

In addition to controlling the operating mode in Standby, the voltage setting can be changed. The transition in voltage is handled in a controlled slope manner, see Serial Interfaces for details. Each regulator has an associated set of SPI bits for Standby mode set points. By default, the Standby settings are identical to the non-standby settings which are initially defined by PUMSx programming.

The actual operating mode of the Switching regulators as a function of the STANDBY pin is not reflected through the SPI. In other words, the SPI will read back what is programmed in SWxMODE[3:0], not the actual state that may be altered as described previously.

Two tables follow for mode control in the low-power Off states. Note that a low-power Off activated SWx should use the Standby set point as programmed by SWxSTBY[4:0]. The activated regulator(s) will maintain settings for mode and voltage until the next start-up event. When the respective time slot of the start-up sequencer is reached for a given regulator, its mode and voltage settings will be updated the same as if starting out of the Off state (except that switching regulators active through a low-power Off mode will not be off when the start-up sequencer is started).

| Table 30. | Switching | regulator Control | In Memory | / Hold |
|-----------|-----------|-------------------|-----------|--------|
|-----------|-----------|-------------------|-----------|--------|

| SW×MHMODE | Memory Hold Operational Mode (38) |
|-----------|-----------------------------------|
| 0 | Off |
| 1 | PFM |

Notes:

 For Memory Hold mode, an activated SWx should use the Standby set point as programmed by SWxSTBY[4:0].

| SWxUOMODE | User Off Operational Mode ⁽³⁹⁾ |
|-----------|---|
| 0 | Off |
| 1 | PFM |

| Table 31. | Switching | regulator | Control In | User Off |
|-----------|-----------|-----------|------------|----------|
|-----------|-----------|-----------|------------|----------|

Notes:

39. For User Off mode, an activated SWx should use the

Standby set point as programmed by SWxSTBY[4:0].

In normal steady state operating mode, the SW1xPWGD pin is high. When the buck charger set point is changed to a higher or lower set point, the SW1xPWGD pin will go low and will go high again when the higher/lower set point is reached.

7.5.4.2 Switching Frequency

A PLL generates the Switching system clocking from the 32.768 kHz crystal oscillator reference. The switching frequency can be programmed to 2.0 MHz or 4.0 MHz by setting the PLLX SPI bit as shown in <u>Table 32</u>.

| Table 32. | Buck Regulator Frequency | |
|-----------|--------------------------|--|
|-----------|--------------------------|--|

| PLLX | Switching Frequency (Hz) |
|------|--------------------------|
| 0 | 2 000 000 |
| 1 | 4 000 000 |

The clocking system provides a near instantaneous activation when the Switching regulators are enabled or when exiting PFM operation for PWM mode. The PLL can be configured for continuous operation with PLLEN = 1.

7.5.4.3 SW1

SW1 is fully integrated synchronous Buck PWM voltage mode control DC/DC regulator. It can be operated in single phase/dual phase mode. The operating mode of the Switching regulators is configured by the SW1CFG pin. The SW1CFG pin is sampled at start-up.

| Table 33. | SW1 | Configuration |
|-----------|-----|---------------|
|-----------|-----|---------------|

| SW1CFG | SW1A/B Configuration Mode |
|----------|---------------------------|
| VCOREDIG | Single Phase Mode |
| Ground | Dual Phase Mode |

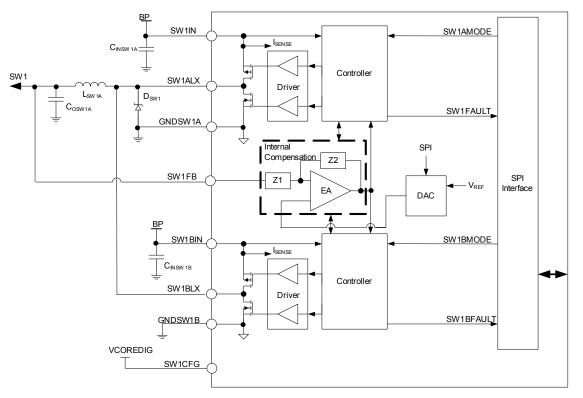

Figure 8. SW1 Single Phase Output Mode Block Diagram

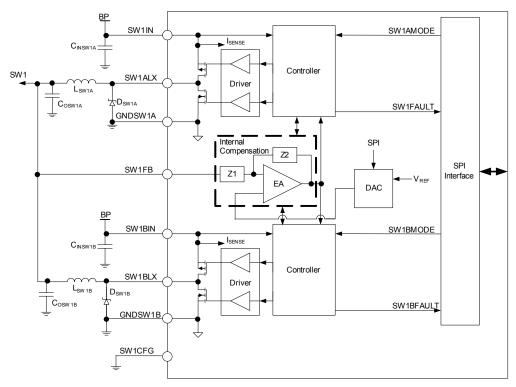

Figure 9. SW1 Dual Phase Output Mode Block Diagram

The peak current is sensed internally for over-current protection purposes. If an over-current condition is detected the regulator will limit the current through cycle by cycle operation and alert the system through the SW1FAULT SPI bit and issue an SCPI interrupt via the INT pin.

SW1A/B output voltage is SPI configurable in step sizes of 12.5 mV as shown in the table below. The SPI bits SW1A[5:0] set the output voltage for both the SW1A and SW1B.

| Set Point | SW1A[5:0] | SW1A/B Output (V) | Set Point | SW1A[5:0] | SW1A/B Output (V) |
|-----------|-----------|----------------------|-----------|-----------|----------------------|
| 0 | 000000 | 0.6500 | 32 | 100000 | 1.0500 |
| 1 | 000001 | 0.6625 | 33 | 100001 | 1.0625 |
| 2 | 000010 | 0.6750 | 34 | 100010 | 1.0750 |
| 3 | 000011 | 0.6875 | 35 | 100011 | 1.0875 |
| 4 | 000100 | 0.7000 | 36 | 100100 | 1.1000 |
| 5 | 000101 | 0.7125 | 37 | 100101 | 1.1125 |
| 6 | 000110 | 0.7250 | 38 | 100110 | 1.1250 |
| 7 | 000111 | 0.7375 | 39 | 100111 | 1.1375 |
| 8 | 001000 | 0.7500 | 40 | 101000 | 1.1500 |
| 9 | 001001 | 0.7625 | 41 | 101001 | 1.1625 |
| 10 | 001010 | 0.7750 | 42 | 101010 | 1.1750 |
| 11 | 001011 | 0.7875 | 43 | 101011 | 1.1875 |
| 12 | 001100 | 0.8000 | 44 | 101100 | 1.2000 |
| 13 | 001101 | 0.8125 | 45 | 101101 | 1.2125 |
| 14 | 001110 | 0.8250 | 46 | 101110 | 1.2250 |
| 15 | 001111 | 0.8375 | 47 | 101111 | 1.2375 |
| 16 | 010000 | 0.8500 | 48 | 110000 | 1.2500 |
| 17 | 010001 | 0.8625 | 49 | 110001 | 1.2625 |
| 18 | 010010 | 0.8750 | 50 | 110010 | 1.2750 |

7.5.4.4 SW2

SW2 is fully integrated synchronous Buck PWM voltage-mode control DC/DC regulator.

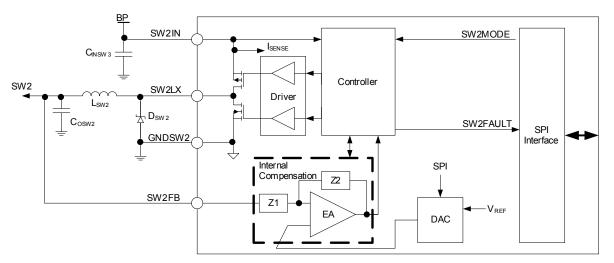

Figure 10. SW2 Block Diagram

The peak current is sensed internally for over-current protection purposes. If an over-current condition is detected, the regulator will limit the current through cycle by cycle operation, alert the system through the SW2FAULT SPI bit, and issue an SCPI interrupt via the INT pin.

SW2 can be programmed in step sizes of 12.5 mV as shown in Table 36.

7.5.4.6 SW4

SW4A/B is fully integrated synchronous Buck PWM voltage mode control DC/DC regulator. It can be operated in (single phase/ dual phase mode) or as separate independent outputs. The operating mode of the Switching regulator is configured by the SW4CFG pin. The SW4CFG pin is sampled at start-up.

Table 40. SW4A/B Configuration

| SW4CFG SW4A/B Configuration Mode | | | |
|----------------------------------|-----------------------------|--|--|
| Ground | Separate independent output | | |
| VCOREDIG | Single phase | | |
| VCORE | Dual phase | | |

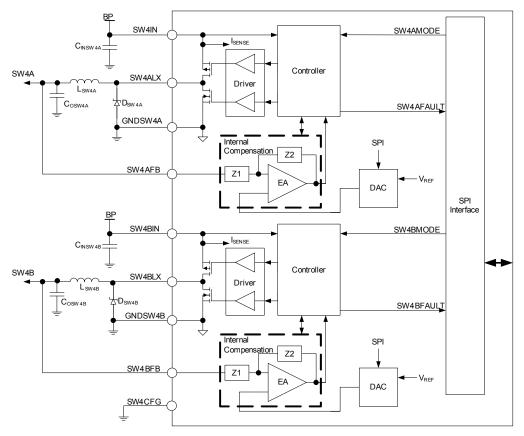

Figure 12. SW4A/B Separate Output Mode Block Diagram

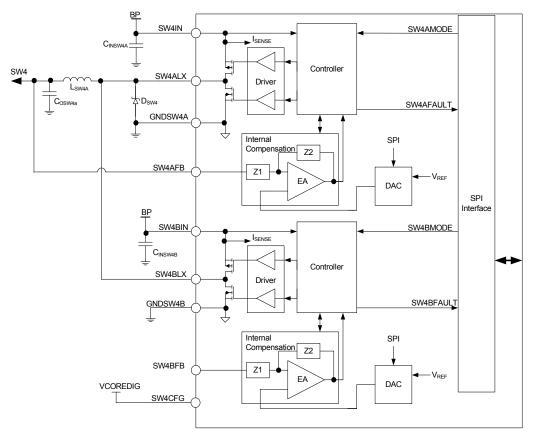

Figure 13. SW4 Single Phase Output Mode Block Diagram

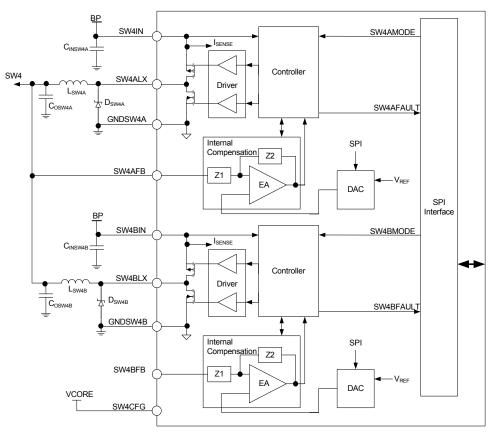

Figure 14. SW4 Dual Phase Output Mode Block Diagram

The peak current is sensed internally for over-current protection purposes. If an over-current condition is detected, the regulator will limit the current through cycle by cycle operation, alert the system through the SW4xFAULT SPI bit, and issue an SCPI interrupt via the INT pin.

SW4A/B has a high output range (2.5 V or 3.15 V) and a low output range (1.2 V to1.85 V). The SW4A/B output range is set by the PUMS configuration at startup and cannot be changed dynamically by software. This means that If the PUMS are set to allow SW4A to come up in the high output voltage range, the output can only be changed between 2.5 V or 3.15 V. It cannot be programmed in the low output range. If software sets the SW4AHI[1:0]= 00, when the PUMS is set to come up into the high voltage range, the output voltage sets the SW4AHI[1:0]= 00, when the PUMS is 2.5 V. If the PUMS are set to start up in the low output voltage range, the voltage is controlled through the SW4x[4:0] bits by software. It cannot be programmed into the high voltage range. When changing the voltage in either the high or low voltage range, the switcher should be forced into PWM mode to change the voltage.

47. When SW4A/B is set to 3.0 V and above the regulator may drop out of regulation when BP nears the output voltage.

48. Efficiency numbers at V_{IN} = 3.6 V, excludes the quiescent current.

7.5.4.7 SW5

SW5 is fully integrated synchronous Buck PWM voltage mode control DC/DC regulator.

Figure 15. SW5 Block Diagram

The peak current is sensed internally for over-current protection purposes. If an over-current condition is detected the regulator will limit the current through cycle by cycle operation and alert the system through the SW5FAULT SPI bit and issue an SCPI interrupt via the INT pin.

SW5 can be programmed in step sizes of 25 mV as shown in <u>Table 44</u>. If the software wants to change the output voltage, after power-up the regulator should be forced into PWM mode to change the voltage.

7.5.4.8 Dynamic Voltage Scaling

To reduce overall power consumption, processor core voltages can be varied depending on the mode or activity level of the processor. SW1A/B and SW2 allow for two different set points with controlled transitions to avoid sudden output voltage changes, which could cause logic disruptions on their loads.

Preset operating points for SW1A/B and SW2 can be set up for:

- Normal operation: output value selected by SPI bits SWx[5:0]. Voltage transitions initiated by SPI writes to SWx[5:0] are governed by the DVS stepping rate shown in the following tables.
- Standby (Deep Sleep): can be higher or lower than normal operation, but is typically selected to be the lowest state retention
 voltage of a given process. Set by SPI bits SWxSTBY[5:0] and controlled by a Standby event. Voltage transitions initiated by
 Standby are governed by the SWxDVSSPEED[1:0] SPI bits shown in <u>Table 46</u>.

The following table summarizes the set point control and DVS time stepping applied to SW1A/B and SW2.

| Table 46. DV | /S Control Logic | Table for SW1A/B | and SW2 |
|--------------|------------------|------------------|---------|
|--------------|------------------|------------------|---------|

| STANDBY | Set Point Selected by |
|---------|-----------------------|
| 0 | SWx[4:0] |
| 1 | SWxSTBY[4:0] |

Table 47. DVS Speed Selection

| SWxDVSSPEED[1:0] | Function |
|------------------|--------------------------------|
| 00 | 12.5 mV step each 2.0 μs |
| 01 (default) | 12.5 mV step each 4.0 μs |
| 10 | 12.5 mV step each 8.0 μ s |
| 11 | 12.5 mV step each 16.0 μs |

The regulator has a strong sourcing and sinking capability in the PWM mode. Therefore, the rising/falling slope is determined by the regulator in PWM mode. However, if the regulators are programmed in PFM, PWMPS, or APS mode during a DVS transition, the falling slope can be influenced by the load. Additionally, as the current capability in PFM mode is reduced, controlled DVS transitions in PFM mode could be affected. Critically timed DVS transitions are best assured with PWM mode operation.

Voltage transitions programmed through SPI(SWx[4:0]) on SW3 and SW5 will step in increments of 25 mV per 4.0 µs, SW4A/B will step in increments of 25 mV per 8.0 µs when SW4xHI[1:0]=00, and SW4A/B will step in increments of 25 mV per 16 µs when SW4xHI[1:0]≠00. Additionally, SW3, SW4/B, and SW5 include standby mode set point programmability.

The following diagram shows the general behavior for the switching regulators when initiated with SPI programming or standby control.

SW1 and SW2 also contain Power Good (outputs from the 34709 to the application processor). The power good signal is an active high signal. When SWxPWRGDB is high, it means that the regulators output has reached its programmed voltage. The SWxPWRGDB voltage outputs will be low during the DVS period and if the current limit is reached on the switching regulator. The SWxPWRGD will be low from a low to high or a high to low transition of the regulator output voltage. During the DVS period, the over-current condition on the switching regulator should be masked. If the current limit is reached outside of a DVS period, the SWxPWRGD pin will stay low until the current limit condition is removed.

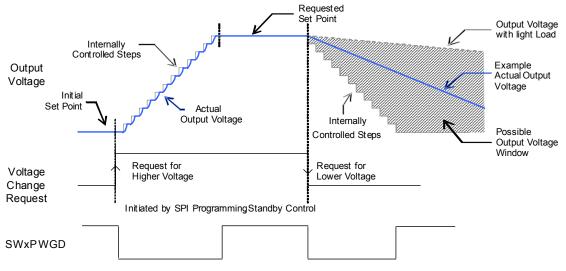

Figure 16. Voltage Stepping with DVS

7.5.5 Boost Switching Regulator

SWBST is a boost switching regulator with a programmable output, which defaults to 5.0 V on power-up, operating at 2.0 MHz. SWBST supplies the VUSB regulator for the USB PHY. Note that the parasitic leakage path for a boost regulator will cause the output voltage SWBSTOUT and SWBSTFB to sit at a Schottky voltage drop below the battery voltage whenever SWBST is disabled. The switching NMOS transistor is integrated on-chip. An external fly back Schottky diode, inductor, and capacitor are required.

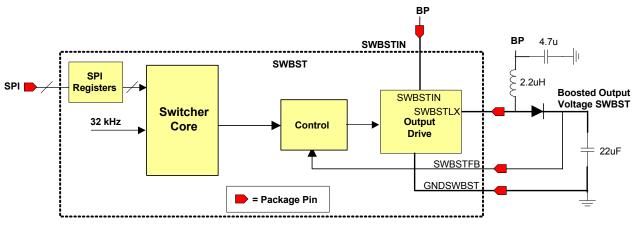

Figure 17. Boost Regulator Architecture

SWBST output voltage programmable via the SWBST[1:0] SPI bits as shown in Table 48.

| Parameter | Voltage | SWBST Output Voltage |
|------------|---------|----------------------|
| | 00 | 5.000 (default) |
| | 01 | 5.050 |
| SWBST[1:0] | 10 | 5.100 |
| | 11 | 5.150 |

Table 48. SWBST Voltage Programming

SWBST can be controlled by SPI programming in PFM, PWM, and Auto mode. Auto mode transitions between PFM and PWM mode based on the load current. By default SWBST is powered up in Auto mode.

7.5.6 Linear Regulators (LDOs)

This section describes the linear regulators provided. For convenience, these regulators are named to indicate their typical or possible applications, but the supplies are not limited to these uses and may be applied to any loads within the specified regulator capabilities.

A low-power standby mode controlled by STANDBY is provided for the regulators with an external pass device in which the bias current is aggressively reduced. This mode is useful for deep sleep operation, where certain supplies cannot be disabled, but active regulation can be tolerated with lesser parametric requirements. The output drive capability and performance are limited in this mode.

All regulators use the main bandgap as reference. The main bandgap is bypassed with a capacitor at REFCORE. The bandgap and the rest of the core circuitry are supplied from VCORE. The performance of the regulators is directly dependent on the performance of VCOREDIG and the bandgap. No external DC loading is allowed on VCOREDIG or REFCORE. VCOREDIG is kept powered as long as there is a valid supply and/or coin cell.

7.5.6.1 General Features

The following applies to all linear regulators, unless otherwise specified.

- · Advised bypass capacitor is the Murata GRM155R60G225ME95, which comes in a 0402 case.
- In general, parametric performance specifications assume the use of low ESR X5R/X7R ceramic capacitors with 20% accuracy and 15% temperature spread, for a worst case stack up of 35% from the nominal value. Use of other types with wider temperature variation may require a larger room temperature nominal capacitance value to meet performance specs over temperature. In addition, capacitor derating as a function of DC bias voltage requires special attention. Finally, minimum bypass capacitor guidelines are provided for stability and transient performance. Larger values may be applied; performance metrics may be altered and generally improved, but should be confirmed in system applications.
- Regulators which require a minimum output capacitor ESR (those with external PNPs) can avoid an external resistor if ESR is assured with capacitor specifications or board level trace resistance.
- The output voltage tolerance specified for each of the linear regulators include process variation, temperature range, static line regulation, and static load regulation.
- In the Low-power mode, the output performance is degraded. Only those parameters listed in the Low-power mode section are guaranteed. In this mode, the output current is limited to much lower currents than in the active mode.
- When a regulator gets disabled, the output will be pulled towards ground by an internal pull-down. The pull-down is also activated when RESETB goes low.

7.5.6.2 LDO Regulator Control

The regulators with embedded pass devices (VPLL, VGEN1, and VUSB) have an adaptive biasing scheme thus, there are no distinct operating modes such as a Normal mode and a Low-power mode. Therefore, no specific control is required to put these regulators in a Low-power mode.

The external pass regulator (VDAC) can also operate in a normal and low-power mode. However, since a load current detection cannot be performed for this regulator, the transition between both modes is not automatic and is controlled by setting the corresponding mode bits for the operational behavior desired.

The regulators VUSB2, and VGEN2 can be configured for using the internal pass device or external pass device as explained in Supplies. For both configurations, the transition between both modes is controlled by setting the VxMODE bit for the specific regulator. Therefore, depending on the configuration selected, the automatic Low-power mode determines availability.

The regulators can be disabled and the general purpose outputs can be forced low when going into Standby (note that the Standby response timing can be altered with the STBYDLY function, as described in the previous section). Each regulator has an associated SPI bit for this. When the bit is not set, STANDBY is of no influence. The actual operating mode of the regulators as a function of STANDBY is not reflected through SPI. In other words, the SPI will read back what is programmed, not the actual state.

| VxEN | VxMODE | VxSTBY | STANDBY ⁽⁵²⁾ | Regulator Vx |
|------|--------|--------|-------------------------|--------------|
| 0 | Х | Х | Х | Off |
| 1 | 0 | 0 | Х | On |
| 1 | 1 | 0 | Х | Low-power |
| 1 | Х | 1 | 0 | On |
| 1 | 0 | 1 | 1 | Off |
| 1 | 1 | 1 | 1 | Low-power |

Table 51. LDO Regulator Control (external pass device LDOs)

Notes

52. STANDBY refers to a Standby event as described earlier

For regulators with internal pass devices, the previous table can be simplified by elimination of the VxMODE column.

| VxEN | VxSTBY | STANDBY ⁽⁵³⁾ | Regulator Vx |
|------|--------|-------------------------|--------------|
| 0 | Х | x | Off |
| 1 | 0 | X | On |
| 1 | 1 | 0 | On |
| 1 | 1 | 1 | Off |

 Table 52. LDO Regulator Control (internal pass device LDOs)

Notes

53. STANDBY refers to a Standby event as described earlier

7.5.6.3 Transient Response Waveforms

The transient load and line response are specified with the waveforms as depicted in <u>Figure 18</u>. Note that where the transient load response refers to the overshoot only, so excluding the DC shift itself, the transient line response refers to the sum of both overshoot and DC shift. This is also valid for the mode transition response.

7.5.6.4 Short-circuit Protection

The higher current LDOs, and those most accessible in product applications, include short-circuit detection and protection (VDAC, VUSB, VUSB2, VGEN1, and VGEN2). The short-circuit protection (SCP) system includes debounced fault condition detection, regulator shutdown, and processor interrupt generation, to contain failures and minimize the chance of product damage. If a short-circuit condition is detected, the LDO will be disabled by resetting its VxEN bit, while at the same time, an interrupt SCPI will be generated to flag the fault to the system processor. The SCPI interrupt is maskable through the SCPM mask bit.

The SCP feature is enabled by setting the REGSCPEN bit. If this bit is not set, then not only is no interrupt generated, but also the regulators will not automatically be disabled upon a short-circuit detection. However, the built-in current limiter will continue to limit the output current of the regulator. Note that by default, the REGSCPEN bit is not set, so at start-up, none of the regulators in an overload condition are disabled.

7.5.6.5 VPLL

VPLL is provided for isolated biasing of the application processors PLLs for clock generation in support of protocol and peripheral needs. Depending on the application and power requirements, this supply may be considered for sharing with other loads, but noise injection must be avoided and filtering added, if necessary to ensure suitable PLL performance. The VPLL regulator has a dedicated input supply pin.

VINPLL can be connected to either BP or a 1.8 V switched mode power supply rail such as from SW5 for the two lower set points of each regulator VPLL[1:0] = [00], [01]. In addition, when the two upper set points (VPLL[1:0] = [10], [11]) are used, the VINPLL inputs can be connected to either BP or a 2.2 V nominal external switched mode power supply rail, to improve power dissipation.

| Parameter | Value | Function | ILoad max | Input Supply |
|-----------|-------|-----------------|-----------|-----------------------|
| | 00 | output = 1.2 V | 50 mA | BP or 1.8 V |
| | 01 | output = 1.25 V | 50 mA | BP or 1.8 V |
| VPLL[1:0] | 10 | output = 1.50 V | 50 mA | BP or External switch |
| | 11 | output = 1.8 V | 50 mA | BP or External switch |

7.5.6.6 VREFDDR

VREFDDR is an internal PMOS half supply Voltage Follower. The output voltage is at one half the input voltage. It's typical application is as the V_{REF} for DDR memories. A filtered resistor divider is utilized to create a low frequency pole. This divider then utilizes a voltage follower to drive the load.

Table 55. VREFDDR Electrical Specification

7.5.6.7 VUSB

The VUSB regulator is used to supply 3.3 V to the external USB PHY, it is powered from the SWBST boost supply to ensure current sourcing compliance through the normal discharge range of the battery/supply input. VUSB has an internal PMOS pass FET which will support loads up to 100 mA.

Table 56. VUSB Electrical Characteristics

Characteristics noted under conditions BP = 3.6 V, -40 °C \leq T_A \leq 85 °C, unless otherwise noted. Typical values at BP = 3.6 V and T_A = 25 °C under nominal conditions, unless otherwise noted.

7.5.6.8 VUSB2

VUSB2 has an internal PMOS pass FET which will support loads up to 65 mA. To support load currents an external PNP is provided. The external PNP configuration is offered to avoid excess on-chip power dissipation at high loads and large differentials between BP and output settings. For lower current requirements, an integrated PMOS pass FET is included. The input pin for the integrated PMOS option is shared with the base current drive pin for the PNP option. The external PNP configuration must be committed as a hardwired board level implementation. The recommended PNP device is the ON Semiconductor™ NSS12100XV6T1G, which is capable of handling up to 250 mW of continuous dissipation, at minimum footprint and 75 °C of ambient. For use cases where up to 500 mW of dissipation is required, the recommended PNP device is the ON Semiconductor NSS12100UW3TCG. For stability reasons, a small minimum ESR may be required.

A short-circuit condition will shut down the VUSB2 regulator and generate an interrupt for SCPI.

The nominal output voltage of this regulator is SPI configurable, and can be 2.5 V, 2.6 V, 2.75 V, or 3.0 V. The output current when working with the internal pass FET is 65 mA, and could be up to 350 mA when working with an external PNP.

7.5.6.9 VDAC

The primary applications of this power supply is the TV-DAC. However, these supplies could also be used for other peripherals if one of these functions is not required. Low-power modes and programmable standby options can be used to optimize power efficiency during deep sleep modes.

An external PNP is utilized for VDAC to avoid excess on-chip power dissipation at high loads and large differentials between BP and output settings. For stability reasons, a small minimum ESR may be required. In the Low-power mode for VDAC, an internal bypass path is used instead of the external PNP. External PNP devices must always be connected to the BP line in the application. The recommended PNP device is the ON Semiconductor NSS12100XV6T1G, which is capable of handling up to 250 mW of continuous dissipation at minimum footprint and 75 °C of ambient. For use cases where up to 500 mW of dissipation is required, the recommended PNP device is the ON Semiconductor NSS12100UW3TCG. For stability reasons, a small minimum ESR may be required.

A short-circuit condition will shut down the VDAC regulator and generate an interrupt for SCPI.

The nominal output voltage of this regulator is SPI configurable, and can be 2.5 V, 2.6 V, 2.7 V, or 2.775 V. The maximum output current along with an external PNP, is 250 mA.

| Parameter | Value | Output Voltage | ILoad max |

7.5.6.10 VGEN1, VGEN2

General purpose LDOs, VGEN1, and VGEN2, are provided for expansion of the power tree to support peripheral devices, which could include EMMC cards, WLAN, BT, GPS, or other functional modules. These regulators include programmable set points for

system flexibility. VGEN1 has an internal PMOS pass FET, and is powered from the SW5 buck for an efficiency advantage and reduced power dissipation in the pass devices. VGEN2 is powered directly from the battery.

VGEN2 has an internal PMOS pass FET, which will support loads up to 50 mA. For higher current capability, drive for an external PNP is provided. The external PNP is offered to avoid excess on-chip power dissipation at high loads and large differentials between BP and output settings. The input pin for the integrated PMOS option is shared with the base current drive pin for the PNP option. The external PNP device is always connected to the BP line in the application. The recommended PNP device is the ON Semiconductor NSS12100XV6T1G which is capable of handling up to 250 mW of continuous dissipation at minimum footprint and 75 °C of ambient. For use cases where up to 500 mW of dissipation is required, the recommended PNP device is the ON Semiconductor NSS12100UW3TCG. For stability, a small minimum ESR may be required.

A short-circuit condition will shut down the VGEN1 and VGEN2 regulators, and generate an interrupt for SCPI.

The nominal output voltage of both VGEN1 and VGEN2 are SPI configurable with the VGENx[2:0] bits as shown in <u>Table 61</u> and <u>Table 62</u>.

7.6 Analog to Digital Converter

The ADC core is a 10 bit converter. The ADC core and logic run at an internally generated frequency of approximately 1.33 MHz. The ADC is supplied from VCORE. The ADC core has an integrated auto calibration circuit which reduces the offset and gain errors.

7.6.1 Input Selector

The ADC has 16 input channels. <u>Table 65</u> gives an overview of the characteristics of each of these channels.

| Table | 65. | ADC | Inputs |
|-------|-----|-----|--------|
|-------|-----|-----|--------|

| Channel | ADSELx[3:0] | Signal read | Input Level | Scaling | Scaled Version |
|---------|-------------|-------------------|--------------|----------|----------------------|
| 0 | 0000 | Reserved | Reserved | Reserved | Reserved |
| 1 | 0001 | Reserved | Reserved | Reserved | Reserved |
| 2 | 0010 | Reserved | Reserved | Reserved | Reserved |
| 3 | 0011 | Die temperature | -40 – 150 °C | | 1.2 – 2.4 V |
| 4 | 0100 | Reserved | Reserved | Reserved | Reserved |
| 5 | 0101 | Reserved | Reserved | Reserved | Reserved |
| 6 | 0110 | Reserved | Reserved | Reserved | Reserved |
| 7 | 0111 | Reserved | Reserved | Reserved | Reserved |
| 8 | 1000 | Coin cell Voltage | 0 – 3.6 V | X2/3 | 0 – 2.4 V |
| 9 | 1001 | ADIN9 | 0 – 2.4 V | x1 | 0 – 2.4 V |
| 10 | 1010 | ADIN10 | 0-2.4 V | x1 | 0 – 2.4 V |
| 11 | 1011 | ADIN11 | 0 – 2.4 V | x1 | 0 – 2.4 V |
| 12 | 1100 | ADIN12/TSX1 | 0 – 2.4 V | x1/x2 | 0 – 2.4 V / 0 -1.2 V |
| 13 | 1101 | ADIN13/TSX2 | 0-2.4 V | x1/x2 | 0 – 2.4 V / 0 -1.2 V |
| 14 | 1110 | ADIN14/TSY1 | 0 – 2.4 V | x1/x2 | 0 – 2.4 V / 0 -1.2 V |
| 15 | 1111 | ADIN15/TSY2 | 0-2.4 V | x1/x2 | 0 – 2.4 V / 0 -1.2 V |

Some of the internal signals are first scaled to adapt the signal range to the input range of the ADC. For details on scaling, see Dedicated Readings.

| Table 66. ADC Input Specification |
|-----------------------------------|
|-----------------------------------|

| Parameter | Condition | | Тур | Max | Units |
|------------------|---------------------------------|---|-----|-----|-------|
| Source Impedance | No bypass capacitor at input | - | - | 5.0 | kOhm |
| Source impedance | Bypass capacitor at input 10 nF | - | - | 30 | kOhm |

When considerately exceeding the maximum input of the ADC at the scaled or unscaled inputs, the reading result will return a full scale. It has to be noted however, that this full scale does not necessarily yield a 1022 DEC reading due to the offsets and calibration applied. The same applies for when going below the minimum input where the corresponding 0000 DEC reading may not be returned.

7.6.2 Control

The ADC parameters are programmed by the processor via the SPI. When a reading sequence is finished, an interrupt ADCDONEI is generated. The interrupt can be masked with the ADCDONEM bit.

The ADC is enabled by setting ADEN bit high. The ADC can start a series of conversions through SPI programming by setting the ADSTART bit. If the ADEN bit is low, the ADC will be disabled and in low-power mode. The ADC is automatically calibrated every time PMIC is powered.

The conversions will begin after a small analog synchronization of up to 30 microseconds, plus a programmable delay from 0 (default) up to 600 μ S, by programming the bits ADDLY1[3:0]. The ADDLY2[3:0] controls the delay between each of the conversions from 0 to 600 μ S. ADDLY3[3:0] controls the delay after the final conversion, and is only valid when ADCONT is high. ADDLY1, 2, and 3 are set to 0 by default.

| ADDLYx[3:0] | Delay in μ s |
|-------------|------------------|
| 0000 | 0.0 |
| 0001 | 40 |
| 0010 | 80 |
| 0011 | 120 |
| 0100 | 160 |
| 0101 | 200 |
| 0110 | 240 |
| 0111 | 280 |
| 1000 | 320 |
| 1001 | 360 |
| 1010 | 400 |
| 1011 | 440 |
| 1100 | 480 |
| 1101 | 520 |
| 1110 | 560 |
| 1111 | 600 |

| Tahlo | 67 | ADDL | VvI | 3.01 |
|-------|-----|------|-----|------|
| able | 01. | ADDL | | 3.0] |

There is a max of 8 conversions that will take place when the ADC is started. The register ADSELx[3:0] selects the channel which the ADC will read and store in the ADRESULTx register. The ADC will always start at the channel indicated in ADSEL0, and read up to and including the channel set by the ADSTOP[2:0] bits. For example, when ADSTOP[2:0] = 010, it will request the ADC to read channels indicated in ADSEL0, ADSEL1, and ADSEL2. When ADSTOP[2:0] = 111, all eight channels programmed by the value in ADSEL0-7 will be read. When the ADCONT bit is set high, it allows the ADC to continuously loop and read the channels from address 0 to the stop address programmed in ADSTOP. By default, the ADCONT is set low (disabled). In the continuous mode, the ADHOLD bit will allow the software to hold the ADC sequencer from updating the results register while the ADC results are read. Once the sequence of A/D conversions is complete, the ADRESULTx results are stored in 4 SPI registers (ADC 4 - ADC 7).

7.6.3 Dedicated Readings

7.6.3.1 Channel 0 to 2 Reserve

Channel 0 to Channel 2 are reserved.

7.6.3.2 Channel 3 Die Temperature

The relation between the read out code and temperature is given in <u>Table 68</u>.

Table 68. Die Temperature Voltage Reading

| Parameter | Min | Тур | Мах | Unit |
|--|-----|--------|-----|---------|
| Die temperature read out code at 25 °C | - | 680 | - | Decimal |
| Slope temperature change per LSB | - | +0.426 | - | °C/LSB |
| Slope error | - | - | 5.0 | % |

The Actual Die Temperature is obtained as follows: Die Temp = 25 + 0.426 * (ADC Code - 680)

7.6.3.3 Channel 4 to 7 Reserved

Channel 4 to Channel 7 are reserved.

7.6.3.4 Channel 8 Coin Cell Voltage

The voltage of the coin cell connected to the LICELL pin can be read on channel 8. Since the voltage range of the coin cell exceeds the input voltage range of the ADC, the LICELL voltage is scaled as V(LICELL)*2/3. In case the voltage at LICELL drops below the coin cell disconnect threshold, the voltage at LICELL can still be read through the ADC.

| Conversion Code ADRESULTx[9:0] | Voltage at ADC input (V) | Voltage at LICELL (V) |
|-----------------------------------|--------------------------|-----------------------|
| 1 111 111 110 | 2.400 | 3.6 |
| 1 000 000 000 | 1.200 | 1.8 |
| 0 000 000 000 | 0.000 | 0 |

Table 69. Coin Cell Voltage Reading Coding

7.6.3.5 Channel 9-11 ADIN9-ADIN11

There are 3 general purpose analog input channels that can be measured through the ADIN9-ADIN11 pins.

7.6.3.6 Channel 12-15 ADIN12-ADIN15

If the touch screen is not used, the inputs TSX1, TSX2, TSY1, and TSY2 can be used as general purpose inputs. They are respectively mapped on ADC channels 12, 13, 14, and 15.

7.6.4 Touch Screen Interface

The touch screen interface provides all circuitry required for the readout of a four-wire resistive touch screen. The touch screen X plate is connected to TSX1 and TSX2, while the Y plate is connected to TSY1 and TSY2. A local supply TSREF will serve as a reference. Several readout possibilities are offered.

If the touchscreen is not used, the inputs TSX1, TSX2, TSY1, and TSY2 can be used as general purpose inputs. They are respectively mapped on ADC channels 12, 13, 14, and 15.

Touch Screen Pen detection bias can be enabled via the TSPENDETEN bit in the AD0 register. When this bit is enabled and a pen touch is detected, the TSPENDET bit in the Interrupt Status 0 register is set and the INT pin is asserted - unless the interrupt is masked. Pen detection is only active when TSEN is low.

The reference for the touch screen (Touch Bias) is TSREF and is powered from VCORE. During touch screen operation, TSREF is a dedicated regulator. No loads other than the touch screen should be connected here. When the ADC performs non touch screen conversions, the ADC does not rely on TSREF and the reference is disabled.

The readouts are designed such that the on chip switch resistances are of no influence on the overall readout. The readout scheme does not account for contact resistances, as present in the touch screen connectors. The touch screen readings will have to be calibrated by the user or the factory, where one has to point with a stylus to the opposite corners of the screen. When reading the X-coordinate, the 10-bit ADC reading represents a 10-bit coordinate, with '0' for a coordinate equal to X-, and full scale '1023' when equal to X+. When reading the Y-coordinate, the 10-bit ADC reading represents a 10-bit coordinate equal to X-, and full scale '1023' when equal to Y-, and full scale '1023' when equal to Y+. When reading contact resistance, the 10-bit ADC reading represents the voltage drop over the contact resistance created by the known current source, multiplied by 2.

The X-coordinate is determined by applying TSREF over the TSX1 and TSX2 pins, while performing a high-impedance reading on the Y-plate through TSY1. The Y-coordinate is determined by applying TSREF between TSY1 and TSY2, while reading the TSX1 pin. The contact resistance is measured by applying a known current into the TSY1 pin of the touch screen and through the TSX2 pin, which is grounded. The voltage difference between the two remaining terminals TSY2 and TSX1 is measured by the ADC, and equals the voltage across the contact resistance. Measuring the contact resistance helps determine if the touch screen is touched with a finger or a stylus.

The TSSELx[1:0] allows the application processor to select its own reading sequence. The TSSELx[1:0] determines what is read during the touch screen reading sequence, as shown in <u>Table 70</u>. The touch screen will always start at TSSEL0 and read up to and including the channel set by TSSEL at the TSSTOP[2:0] bits. For example when TSSTOP[2:0] = 010, it will request the ADC to read channels indicated in TSSEL0, TSSEL1, and TSSEL2. When TSSTOP[2:0] = 111, all eight addresses will be read.

| TSSELx[1:0] | Signals Sampled |
|-------------|------------------------------|
| 00 | Dummy to discharge TSREF cap |
| 01 | X - plate |
| 10 | Y - plate |
| 11 | Contact |

Table 70. Touch Screen Action Select

The touch screen readings can be repeated, as in the following example readout sequence, to reduce the interrupt rate and to allow for easier noise rejection. The dummy conversion inserted between the different readings allows the references in the system to be pre-biased for the change in touch screen plate polarity. It will read out as '0'.

A touch screen reading will take precedence over an ADC sequence. If an ADC reading is triggered during a touch screen event, the ADC sequence will be overwritten by the touch screen data.

The first touch screen conversion can be delayed from 0 (default) to 600 μ s by programming the TSDLY1[3:0] bits. The TSDLY2[3:0] controls the delay between each of the touch screen conversions from 0 to 600 μ s. TSDLY[2:0] sets the delay after the last address is converted. TSDLY1, 2, and 3 are set to 0 by default.

| Delay in uS |
|-------------|
| 0 |
| 40 |
| 80 |
| 120 |
| 160 |
| 200 |
| 240 |
| |

| Table 71. | TSDLYx[3:0] |
|-----------|-------------|
|-----------|-------------|

| TSDLYx[3:0] | Delay in uS |
|-------------|-------------|
| 0111 | 280 |
| 1000 | 320 |
| 1001 | 360 |
| 1010 | 400 |
| 1011 | 440 |
| 1100 | 480 |
| 1101 | 520 |
| 1110 | 560 |
| 1111 | 600 |
| - | |

Table 71. TSDLYx[3:0]

To perform a touch screen reading, the processor must do the following:

- 1. Enable the touch screen with TSEN
- 2. Select the touch screen sequence by programming the TSSEL0-TSSEL7 SPI bits.
- 3. Program the TSSTOP[2:0]
- 4. Program the delay between the conversion via the TSDLY1 and TSDLY2 settings.
- 5. Trigger the ADC via the TSSTART SPI bit
- 6. Wait for an interrupt indicating the conversion is done TSDONEI
- 7. And then read out the data in the ADRESULTx registers

7.6.5 ADC Specifications

Table 72. ADC Electrical Specifications

Characteristics noted under conditions BP = 3.6 V, -40 °C \leq T_A \leq 85 °C, unless otherwise noted. Typical values at BP = 3.6 V and T_A = 25 °C under nominal conditions, unless otherwise noted.

7.7 Auxiliary Circuits

7.7.1 General Purpose I/Os

The 34709 contains four configurable GPIO input/outputs for general purpose use. When configured as outputs, they can be configured as open-drain (OD) or CMOS (push-pull outputs). These GPIOs are low-voltage capable (1.2 or 1.8 V). In open-drain configuration these outputs can only be pulled up to 2.5 V maximum.

Each individual GPIO has a dedicated 16-bit control register. Table 73 provides detailed bit descriptions.

| SPI Bit | Description |
|-----------|--|
| DIR | GPIOLVx direction 0: Input (default) 1: Output |
| DIN | Input state of the GPIOLVx pin 0: Input low 1: Input High |
| DOUT | Output state of GPIOLVx pin 0: Output Low 1: Output High |
| HYS | Hysteresis 0: CMOS in 1: Hysteresis (default) |
| DBNC[1:0] | GPIOLVx input debounce time 00: no debounce (default) 01: 10 ms debounce 10: 20 ms debounce 11: 30 mS debounce |

| Notes 55. x= 0, 1, 2, or 3 depending of the GPIO channel it is being used | |

7.7.2 PWM Outputs

There are two PWM outputs on the 34709 PWM1 and PWM2 and which are controlled by the PWMxDUTY and PWMxCLKDIV registers shown in <u>Table 74</u>. The base clock will be the 2.0 MHz divided by 32.

| PWMxDC[5:0](⁽⁵⁶⁾) | Duty Cycle |
|--------------------------------|------------------------|
| 000000 | 0/32, Off (default) |
| 000001 | 1/32 |
| | |
| 010000 | 16/32 |
| | |
| 011111 | 31/32 |
| 1xxxxx | 32/32, Continuously On |

7.8 Serial Interfaces

The IC contains a number of programmable registers for control and communication. The majority of registers are accessed through a SPI interface in a typical application. The same register set may alternatively be accessed with an I^2C interface that is muxed on SPI pins. <u>Table 76</u> describes the muxed pin options for the SPI and I^2C interfaces; further details for each interface mode follow.

Table 76. SPI / I²C Bus Configuration

| Pin Name | SPI Mode Functionality | I ² C Mode Functionality |
|----------|---|--------------------------------------|
| CS | Configuration ⁽⁵⁸⁾ , Chip Select | Configuration ⁽⁵⁹⁾ |
| CLK | SPI Clock | SCL: I ² C bus clock |
| MISO | Master In, Slave Out (data output) | SDA: Bi-directional serial data line |
| MOSI | Master Out, Slave In (data input) | A0 Address selection ⁽⁶⁰⁾ |

Notes

58. CS held low at Cold Start, configures the interface for SPI mode; once activated, CS functions as the SPI Chip Select.

59. CS tied to VCOREDIG at Cold Start, configures the interface for I^2C mode; the pin is not used in I^2C mode, other than for configuration.

60. In I²C mode, the MOSI pin is hardwired to ground, or VCOREDIG is used to select between two possible addresses.

7.8.1 SPI Interface

The IC contains a SPI interface port which allows access by a processor to the register set. Via these registers the resources of the IC can be controlled. The registers also provide status information about how the IC is operating, as well as information on external signals.

Because the SPI interface pins can be reconfigured for reuse as an I^2C interface, a configuration protocol mandates that the CS pin is held low during a turn on event for the IC (a weak pull-down is integrated on the CS pin). The state of CS is latched in during the initialization phase of a Cold Start sequence, ensuring that the I^2C bus is configured before the interface is activated. With the CS pin held low during start-up (as would be the case if connected to the CS driver of an unpowered processor due to the integrated pull-down), then the bus configuration will be latched for SPI mode.

The SPI port utilizes 32-bit serial data words comprised of 1 write/read_b bit, 6 address bits, 1 null bit, and 24 data bits. The addressable register map spans 64 registers of 24 data bits each. The map is not fully populated, but it follows the legacy conventions for bit positions corresponding to common functionality with previous generation FSL products.

7.8.1.1 SPI Interface Description

For a SPI read, the first bit sent to the IC must be a zero indicating a SPI read cycle. Next, the six bit address is sent MSB first. This is followed by one dead bit to allow for more address decode time. The 34709 will clock the above bits in on the rising edge of the SPI clock. Then the 24 data bits are driven out on the MISO pin on the falling edge of the SPI clock so the master can clock them in on the rising edge of the SPI clock.

For each MOSI SPI transfer, first a one is written to the write/read_b bit if this SPI transfer is to be a write. A zero is written to the write/read_b bit if this is to be a read command. If a zero is written, then any data sent after the address bits are ignored and the internal contents of the field addressed do not change when the 32nd CLK is sent.

For a SPI write the first bit sent to the 34709 must be a one indicating a SPI write cycle. Next the six bit address is sent MSB first. This is followed by one dead bit to allow for more address decode time. Then the data is sent MSB first. The SPI data is written to the SPI register whose address was sent at the start of the SPI cycle on the falling edge of the 32nd SPI clock. Additionally, whenever a SPI write cycle is taking place the SPI read data is shifted out for the same address as for the write cycle. Next the 6-bit address is written, MSB first. Finally, data bits are written, MSB first. Once all the data bits are written then the data is transferred into the actual registers on the falling edge of the 32nd CLK.

The CS polarity is active high. The CS line must remain high during the entire SPI transfer. For a write sequence it is possible for the written data to be corrupted, if after the falling edge of the 32nd clock the CS goes low before it's required time. CS can go low before this point and the SPI transaction will be ignored, but after that point the write process is started and cannot be stopped because the write strobe pulse is already being generated and CS going low may cause a runt pulse that may or may not be wide enough to clock all 24 data bits properly. To start a new SPI transfer, the CS line must be toggled low and then pulled high again. The MISO line will be tri-stated while CS is low.

The register map includes bits that are read/write, read only, read/write "1" to clear (i.e., Interrupts), and clear on read, reserved, and unused. Refer to the SPI/I2C Register Map and the individual subcircuit descriptions to determine the read/write capability of each bit. All unused SPI bits in each register must be written to as zeroes. A SPI read back of the address field and unused bits are returned as zeroes. To read a field of data, the MISO pin will output the data field pointed to by the 6 address bits loaded at the beginning of the SPI sequence.

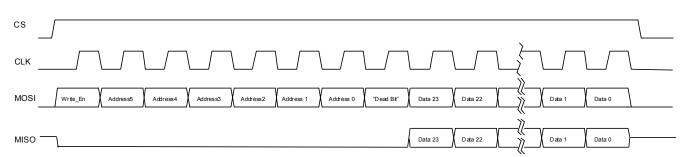

Figure 19. SPI Transfer Protocol Single Read/Write Access

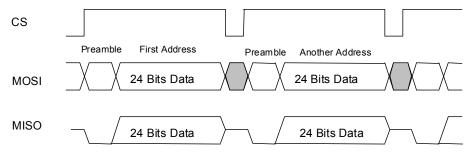

Figure 20. SPI Transfer Protocol Multiple Read/Write Access

7.8.1.2 SPI Timing Requirements

Figure 21 and Table 77 summarize the SPI timing requirements. The SPI input and output levels are set via the SPIVCC pin, by connecting it to the desired supply. This would typically be tied to SW5 and programmed for 1.80 V. The strength of the MISO driver is programmable through the SPIDRV [1:0] bits. See Thermal Protection Thresholds for detailed SPI electrical characteristics.

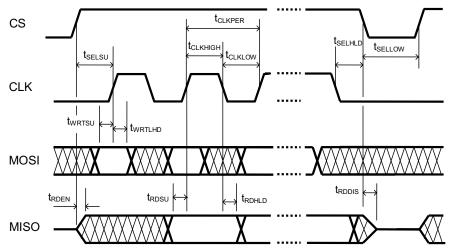

Figure 21. SPI Interface Timing Diagram

| Parameter | Description | t _{MIN} (ns) |
|----------------------|---|-----------------------|
| t _{SELSU} | Time CS has to be high before the first rising edge of CLK | 15 |
| t _{SELHLD} | Time CS has to remain high after the last falling edge of CLK | 15 |
| t _{SELLOW} | Time CS has to remain low between two transfers | 15 |
| t _{CLKPER} | Clock period of CLK | 38 |
| t _{CLKHIGH} | Part of the clock period where CLK has to remain high | 15 |
| t _{CLKLOW} | Part of the clock period where CLK has to remain low | 15 |
| twrtsu | Time MOSI has to be stable before the next rising edge of CLK | 4.0 |
| t _{WRTHLD} | Time MOSI has to remain stable after the rising edge of CLK | 4.0 |
| t _{RDSU} | Time MISO will be stable before the next rising edge of CLK | 4.0 |
| t _{RDHLD} | Time MISO will remain stable after the falling edge of CLK | 4.0 |
| t _{RDEN} | Time MISO needs to become active after the rising edge of CS | 4.0 |
| t _{RDDIS} | Time MISO needs to become inactive after the falling edge of CS | 4.0 |

Table 77. SPI Interface Timing Specifications⁽⁶¹⁾

Notes

61. This table reflects a maximum SPI clock frequency of 26 MHz.

7.8.2 I²C Interface

7.8.2.1 I²C Configuration

When configured for I²C mode, the interface may be used to access the complete register map previously described for SPI access. Since SPI configuration is more typical, references within this document will generally refer to the common register set as a "SPI map" and bits as "SPI bits"; however, it should be understood that access reverts to I²C mode when configured as such.

The SPI pins CLK and MISO are reused for the SCL and SDA lines respectively. Selection of I^2C mode for the interface is configured by hard-wiring the CS pin to VCOREDIG on the application board. The state of CS is latched in during the initialization phase of a Cold Start sequence, so the I^2CS bit is defined for bus configuration before the interface is activated. The pull-down on CS will be deactivated if the high state is detected (indicating I^2C mode).

In I^2C mode, the MISO pin is connected to the bus as an open-drain driver, and the logic level is set by an external pull-up. The part can function only as an I^2C slave device, not as a host.

7.8.2.2 I²C Device ID

I²C interface protocol requires a device ID for addressing the target IC on a multi-device bus. To allow flexibility in addressing for bus conflict avoidance, pin programmable selection is provided to allow configuration for the address LSB(s). This product supports 7-bit addressing only; support is not provided for 10-bit or general Call addressing.

Because the MOSI pin is not utilized for I²C communication, it is reassigned for pin programmable address selection by hardwiring to VCOREDIG or GND at the board level when configured for I²C mode. MOSI will act as Bit 0 of the address. The I²C address assigned to FSL PM ICs (shared amongst our portfolio) is given as follows:

00010-A1-A0, the A1 and A0 bits are allowed to be configured for either 1 or 0. The A1 address bit is internally hardwired as a "0", leaving the LSB A0 for board level configuration. The designated address then is defined as: 000100-A0.

7.8.2.3 I²C Operation

The I²C mode of the interface is implemented generally following the Fast Mode definition which supports up to 400 kbits/s operation. (Exceptions to the standard are noted to be 7-bit only addressing, and no support for general Call addressing) Timing diagrams, electrical specifications, and further details on this bus standard, is available on the internet, by typing "I²C specification" in the web search string field.

Standard I²C protocol utilizes bytes of eight bits, with an acknowledge bit (ACK) required between each byte. However, the number of bytes per transfer is unrestricted. The register map is organized in 24-bit registers which corresponds to the 24-bit words supported by the SPI protocol of this product. To ensure that I²C operation mimics SPI transactions in behavior of a complete 24-bit word being written in one transaction, software is expected to perform write transactions to the device in 3-byte sequences, beginning with the MSB. Internally, data latching will be gated by the acknowledge at the completion of writing the third consecutive byte.

Failure to complete a 3-byte write sequence will abort the l^2C transaction and the register will retain its previous value. This could be due to a premature STOP command from the master, for example.

I²C read operations are also performed in byte increments separated by an ACK. Read operations also begin with the MSB and 3-bytes will be sent out unless a STOP command or NACK is received prior to completion.

The following examples show how to write and read data to the IC. The host initiates and terminates all communication. The host sends a master command packet after driving the start condition. The device will respond to the host if the master command packet contains the corresponding slave address. In the following examples, the device is shown always responding with an ACK to transmissions from the host. If at any time a NAK is received, the host should terminate the current transaction and retry the transaction.

7.9 Configuration Registers

7.9.1 Register Set structure

The general structure of the register set is given in <u>Table 79</u>. Expanded bit descriptions are included in the following functional sections for application guidance. For brevity's sake, references are occasionally made herein to the register set as the "SPI map" or "SPI bits", but note that bit access is also possible through the I²C interface option so such references are implied as generically applicable to the register set accessible by either interface.

| | Register | | Register | | Register | | Register |
|----|-----------------------|----|---------------------------|----|------------------|----|-----------------|
| 0 | Interrupt Status 0 | 16 | Memory A | 32 | Regulator Mode 0 | 48 | ADC5 |
| 1 | Interrupt Mask 0 | 17 | Memory B | 33 | GPIOLV0 Control | 49 | ADC6 |
| 2 | Interrupt Sense 0 | 18 | Memory C | 34 | GPIOLV1 Control | 50 | ADC7 |
| 3 | Interrupt Status 1 | 19 | Memory D | 35 | GPIOLV2 Control | 51 | Reserved |

Table 79. Register Set

7.9.2 Specific Registers

7.9.2.1 IC and Version Identification

The IC and other version details can be read via the identification bits. These are hardwired on the chip and described in Table 80.

| Identifier | Value | Purpose |
|----------------------|-------|--|
| FULL_LAYER_REV[2:0] | XXX | Represents the full mask revision Pass 1.0 = 001 |
| METAL_LAYER_REV[2:0] | xxx | Represents the full Metal revision Pass 1.0 = 000 |
| FIN[2:0] | 000 | Options within same Reticle Pass 1.0 = 000 |
| FAB[2:0] | 000 | Wafer manufacturing facility Pass 1.0 = 000 |

Table 80. IC Revision Bit Assignment

7.9.2.2 Embedded Memory

There are four register banks of general purpose embedded memory to store critical data. The data written to MEMA[23:0], MEMB[23:0], MEMC[23:0], and MEMD[23:0] is maintained by the coin cell when the main battery is deeply discharged, removed, or contact-bounced (i.e., during a power cut). The contents of the embedded memory are reset by RTCPORB. A known pattern can be maintained in these registers to validate confidence in the RTC contents when power is restored after a power cut event. Alternatively, the banks can be used for any system need for bit retention with coin cell backup.

7.9.3 SPI/I²C Register Map

The complete SPI bitmap is given in Table 81.

Table 81. SPI/I²C Register Map

| | Register Types | Register Values | Reset |
|------|---------------------|-----------------|---|
| R/W | Read / Write | 0 = low | Bits Loaded at Cold Start based on PUMS Value |

Table 117. Register 37 - 40, Reserved

| Name | Bit # | R/W | Reset | Default | Description |
|--------|--------|-----|-------|---------|---------------|
| Unused | 0 - 23 | R | | 0 | Not available |

Table 118. Register 41 - 42, Unused

| Name | Bit # | R/W | Reset | Default | Description |
|--------|-------|-----|-------|---------|---------------|
| Unused | 0-23 | R | | 0 | Not available |

Table 119. Register 43, ADC 0

| Name | Bit # | R/W | Reset | Default | Description |
|----------------|-------|-----|-----------|---------|--|
| ADEN | 0 | R/W | DIGRESETB | 0 | Enables ADC from the low-power mode |
| ADSTART | 1 | R/W | DIGRESETB | 0 | Request a start of the ADC Reading Sequencer |
| ADCONT | 2 | R/W | DIGRESETB | 0 | Run ADC reads continuously when high or one time when low. Note that the TSSTART request will have higher priority |
| ADHOLD | 3 | R/W | DIGRESETB | 0 | Hold the ADC reading Sequencer while saved ADC results are read from SPI |
| ADSTOP0 | 4 | R/W | DIGRESETB | 0 | |
| ADSTOP1 | 5 | R/W | DIGRESETB | 0 | Channel Selection to stop when complete. Always start at 000 and read up to and including this channel value. |
| ADSTOP2 | 6 | R/W | DIGRESETB | 0 | |
| Spare | 7 | R/W | DIGRESETB | 0 | Not available |
| THERM | 8 | R/W | DIGRESETB | 0 | 0: NTCREF not forced on 1: Force NTCREF on |
| Spare | 9 | R/W | DIGRESETB | 0 | Not available |
| Spare | 10 | R/W | DIGRESETB | 0 | Not available |
| Spare | 11 | R/W | DIGRESETB | 0 | Not available |
| TSEN | 12 | R/W | DIGRESETB | 0 | Enable the touch screen from low-power mode. |
| TSSTART | 13 | R/W | DIGRESETB | 0 | Request a start of the ADC Reading Sequencer for touch screen readings. |
| TSCONT | 14 | R/W | DIGRESETB | 0 | Run ADC reads of touch screen continuously when high or one time when low. |
| TSHOLD | 15 | R/W | DIGRESETB | 0 | Hold the ADC reading Sequencer while saved touch screen results are read from SPI |
| TSSTOP0 | 16 | R/W | DIGRESETB | 0 | Just like the ADSTOP above, but for the touch screen read programming. This will |
| TSSTOP1 | 17 | R/W | DIGRESETB | 0 | allow independent code for ADC Sequence readings and touch screen ADC |
| TSSTOP2 | 18 | R/W | DIGRESETB | 0 | Sequence readings. |
| Spare | 19 | R/W | DIGRESETB | 0 | Not available |
| TSPENDET EN | 20 | R/W | DIGRESETB | 0 | Enable the touch screen Pen Detection. Note that TSEN must be off for Pen Detection. |
| Spare | 21 | R/W | DIGRESETB | 0 | Not available |
| Spare | 22 | R/W | DIGRESETB | 0 | Not available |
| Spare | 23 | R/W | DIGRESETB | 0 | Not available |

Back to SPI/I2C Register Map

Table 120. Register 44, ADC 1

| Name | Bit # | R/W | Reset | Default | Description |
|---------|-------|-----|-----------|---------|--|
| ADDLY10 | 0 | R/W | DIGRESETB | 0 | |
| ADDLY11 | 1 | R/W | DIGRESETB | 0 | This will allow delay before the ADC readings |
| ADDLY12 | 2 | R/W | DIGRESETB | 0 | This will allow delay before the ADC readings. |
| ADDLY13 | 3 | R/W | DIGRESETB | 0 | |

Table 120. Register 44, ADC 1

| Name | Bit # | R/W | Reset | Default | Description |
|---------|-------|-----|-----------|---------|---|
| ADDLY20 | 4 | R/W | DIGRESETB | 0 | |
| ADDLY21 | 5 | R/W | DIGRESETB | 0 | |
| ADDLY22 | 6 | R/W | DIGRESETB | 0 | This will allow delay between each of ADC readings in a set. |
| ADDLY23 | 7 | R/W | DIGRESETB | 0 | |
| ADDLY30 | 8 | R/W | DIGRESETB | 0 | |
| ADDLY31 | 9 | R/W | DIGRESETB | 0 | This will allow delay after the set of ADC readings. This delay is only valid between |
| ADDLY32 | 10 | R/W | DIGRESETB | 0 | subsequent wrap around reading sequences with ADCONT |
| ADDLY33 | 11 | R/W | DIGRESETB | 0 | |
| TSDLY10 | 12 | R/W | DIGRESETB | 0 | |
| TSDLY11 | 13 | R/W | DIGRESETB | 0 | This will allow delay before the ADC touch screen readings. This is like the ADDLY1, |
| TSDLY12 | 14 | R/W | DIGRESETB | 0 | but allows independent programming of touch screen readings from general purpose ADC readings to prevent code replacement in the system. |
| TSDLY13 | 15 | R/W | DIGRESETB | 0 | |
| TSDLY20 | 16 | R/W | DIGRESETB | 0 | |
| TSDLY21 | 17 | R/W | DIGRESETB | 0 | This will allow delay between each of ADC touch screen readings in a set. This is like the ADDLY2, but allows independent programming of touch screen readings from |
| TSDLY21 | 18 | R/W | DIGRESETB | 0 | general purpose ADC readings to prevent code replacement in the system. |
| TSDLY23 | 19 | R/W | DIGRESETB | 0 | |
| TSDLY30 | 20 | R/W | DIGRESETB | 0 | This will allow delay after the set of ADC touch screen readings. This delay is only |
| TSDLY31 | 21 | R/W | DIGRESETB | 0 | valid between subsequent wrap around reading sequences with TSCONT mode |
| TSDLY31 | 22 | R/W | DIGRESETB | 0 | This is like the ADDLY3, but allows independent programming of touch screen readings from general purpose ADC readings to prevent code replacement in the |
| TSDLY33 | 23 | R/W | DIGRESETB | 0 | system. |

53 Notes

69. Freescale does not assume liability, endorse, or warrant components from external manufacturers that are referenced in circuit drawings or tables. While Freescale offers component recommendations in this configuration, it is the customer's responsibility to validate their application.

8.3 34709 Layout Guidelines

8.3.1 General board recommendations

- 1. It is recommended to use an 4 layer board stack-up arranged as follows:
- · High-current signal

- GND
- Signal
- · High-current signal
- 2. Allocate TOP and BOTTOM PCB Layers for POWER ROUTING (high-current signals), copper-pour the unused area.
- 3. Add one GND inner layer to reduce Current loops to the maximum between layers.

8.3.2 **General Routing Requirements**

- 1. Some recommended things to keep in mind for manufacturability:
- Via in pads require a 4.5 mil Minimum annular ring. Pad must be 9.0 mils larger than the hole
- Max copper thickness for lines less than 5.0 mils wide is 0.6 oz copper
- · Minimum allowed spacing between line and hole pad is 3.5 mils
- · Minimum allowed spacing between line and line is 3.0 mils
- 2. Care must be taken with SWxFB pins traces. These signals are susceptible to noise and must be routed far away from power, clock, or high-power signals, like the ones on the SWxIN, SWx, SWxLX, SWBSTIN, SWBST, and SWBSTLX pins.

- 3. Shield feedback traces of the switching regulators and keep them as short as possible (trace them on the bottom so the ground and power planes shield these traces).
- 4. Avoid coupling trace between important signal/low noise supplies (like VREFCORE, VCORE, VCOREDIG) from any switching node (i.e. SW1ALXx, SW2LX, SW3LX, SW4ALX, SW4BLX, SW5LX, and SWBSTLX).
- 5. Make sure that all components related to an specific block are referenced to the corresponding ground, e.g. all components related to the SW1 converter must referenced to GNDSW1A1 and GNDSW1A2.

8.3.3 Parallel Routing Requirements

- 1. SPI/I²C signal routing:
- CLK is the fastest signal of the system, so it must be given special care. Here are some tips for routing the communication signals:
- To avoid contamination of these delicate signals by nearby high-power or high-frequency signals, it is a good practice to shield them with ground planes placed on adjacent layers. Make sure the ground plane is uniform throughout the whole signal trace length.

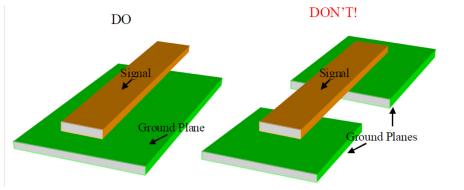

Figure 25. Recommended Shielding for Critical Signals.

- These signals can be placed on an outer layer of the board to reduce their capacitance in respect to the ground plane.
- The crystal connected to the XTAL1 and XTAL2 pins must not have a ground plane directly below.
- The following are clock signals: CLK, CLK32K, CLK32KMCU, XTAL1, and XTAL2. These signals must not run parallel to
 each other, or in the same routing layer. If it is necessary to run clock signals parallel to each other, or parallel to any other
 signal, then follow a MAX PARALLEL rule as follows:
 - Up to one inch parallel length 25 mil minimum separation
 - Up to two inches parallel length 50 mil minimum separation
 - Up to three inches parallel length 100 mil minimum separation
 - Up to four inches parallel length 250 mil minimum separation
- Care must be taken with these signals not to contaminate analog signals, as they are high-frequency signals. Another good practice is to trace them perpendicularly on different layers, so there is a minimum area of proximity between signals.

8.3.4 Switching Regulator Layout Recommendations

- 1. Per design, the 34709 is designed to operate with only one input bulk capacitor. However, it is recommended to add a high-frequency filter input capacitor (CIN_hf), to filter out any noise at the regulator input. This capacitor should be in the range of 100 nF and should be placed right next to or under the IC, closest to the IC pins.
- 2. Make high-current ripple traces low inductance (short, high W/L ratio).
- 3. Make high-current traces wide or copper islands.
- 4. Make high-current traces SYMETRICAL for dual-phase regulators (SW1, SW4).

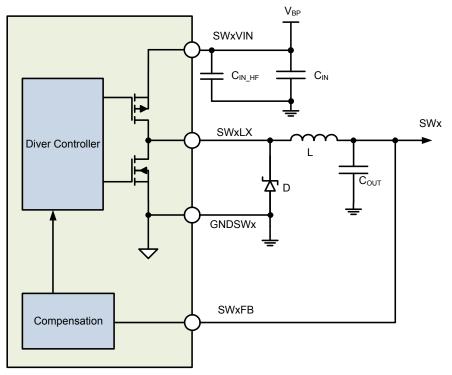

Figure 26. Generic Buck Regulator Architecture

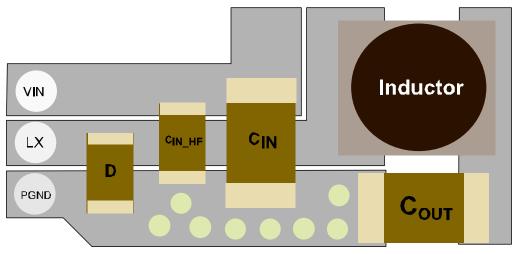

Figure 27. Recommended Layout for Switching Regulators.

8.4 Thermal Considerations

8.4.1 Rating Data

The thermal rating data of the packages has been simulated with the results listed in Table 5.

Junction to Ambient Thermal Resistance Nomenclature: the JEDEC specification reserves the symbol $R_{\theta JA}$ or θJA (Theta-JA) strictly for junction-to-ambient thermal resistance on a 1s test board in natural convection environment. $R_{\theta JMA}$ or θJMA (Theta-JMA) will be used for both junction-to-ambient on a 2s2p test board in natural convection and for junction-to-ambient with

forced convection on both 1s and 2s2p test boards. It is anticipated that the generic name, Theta-JA, will continue to be commonly used.

The JEDEC standards can be consulted at http://www.jedec.org/

8.4.2 Estimation of Junction Temperature

An estimation of the chip junction temperature TJ can be obtained from the equation

 $T_J = T_A + (R_{\theta JA} \times P_D)$

with

T_A = Ambient temperature for the package in °C

 $R_{\theta,JA}$ = Junction to ambient thermal resistance in °C/W

P_D = Power dissipation in the package in W

The junction to ambient thermal resistance is an industry standard value that provides a quick and easy estimation of thermal performance. Unfortunately, there are two values in common usage: the value determined on a single layer board $R_{\theta JA}$ and the value obtained on a four layer board $R_{\theta JMA}$. Actual application PCBs show a performance close to the simulated four layer board value although this may be somewhat degraded in case of significant power dissipated by other components placed close to the device.

At a known board temperature, the junction temperature T_J is estimated using the following equation

 $T_J = T_B + (R_{\theta JB} \times P_D)$ with

T_B = Board temperature at the package perimeter in °C

 $R_{\theta JB}$ = Junction to board thermal resistance in °C/W

P_D = Power dissipation in the package in W

When the heat loss from the package case to the air can be ignored, acceptable predictions of junction temperature can be made.

See Functional Block Description for more details on thermal management.

9 Packaging

The 34709 is offered in an 130 balls, 8.0x8.0 mm, 0.5 mm pitch MAPBGA package.

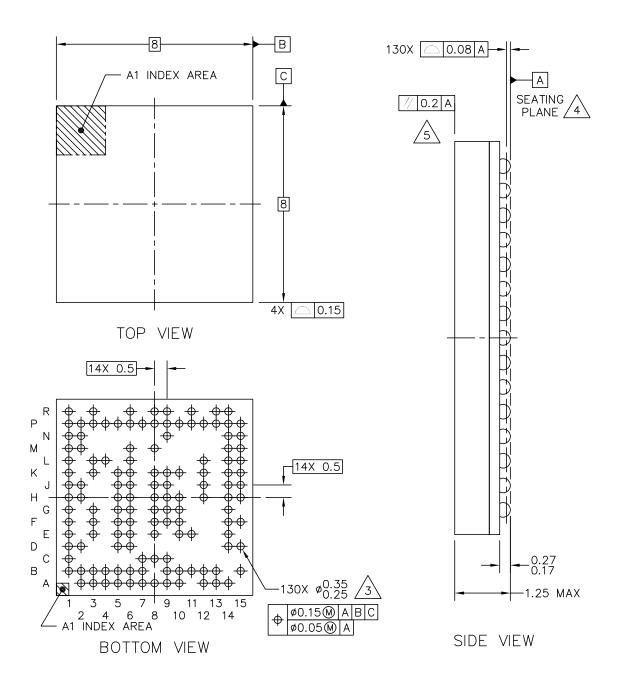

9.1 Package Mechanical Dimensions

Package dimensions are provided in package drawings. To find the most current package outline drawing, go to www.freescale.com and perform a keyword search for the drawing's document number.

Table 133. Package Drawing Information
