## Oscillator Frequency Upconverter

## FEATURES

Converts a low frequency input reference signal to a high frequency output signal
Input frequencies from 6.6 MHz to 112.5 MHz
Output frequencies up to $900 \mathbf{M H z}$
Preset pin programmable frequency translation ratios
Arbitrary frequency translation ratios via SPI port
On-chip VCO
Accepts a crystal resonator and/or an external oscillator as a reference frequency source
Secondary output (either integer-related to the primary output or a copy of the reference input)
RMS jitter: <0.5 ps
SPI-compatible, 3 -wire programming interface
Single supply ( 3.3 V )
Very low power: $<\mathbf{4 0 0} \mathbf{~ m W}$ (under most conditions)
Small package size ( $5 \mathrm{~mm} \times 5 \mathrm{~mm}$ )

## APPLICATIONS

Cost effective replacement of high frequency VCXO, OCXO, and SAW resonators
Extremely flexible frequency translation with low jitter for SONET/SDH (including FEC), 10 Gb Ethernet, Fibre Channel, and DRFI/DOCSIS
High-definition video frequency translation
Wireless infrastructure
Test and measurement (including handheld devices)

## GENERAL DESCRIPTION

The AD9552 is a fractional-N phase locked loop (PLL) based clock generator designed specifically to replace high frequency crystal oscillators and resonators. The device employs a sigmadelta ( $\Sigma-\Delta$ ) modulator (SDM) to accommodate fractional frequency synthesis. The user supplies an input reference signal by connecting a single-ended clock signal directly to the REF pin or by connecting a crystal resonator across the XTAL pins.

The AD9552 is pin programmable, providing one of 64 standard output frequencies based on one of eight common input frequencies. The device also has a 3-wire SPI interface, enabling the user to program custom input-to-output frequency ratios.

The AD9552 relies on an external capacitor to complete the loop filter of the PLL. The output is compatible with LVPECL, LVDS, or single-ended CMOS logic levels, although the AD9552 is implemented in a strictly CMOS process.
The AD9552 is specified to operate over the extended industrial temperature range of $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$.

## SPECIFICATIONS

Minimum (min) and maximum (max) values apply for the full range of supply voltage and operating temperature variations. Typical (typ) values apply for $\mathrm{VDD}=3.3 \mathrm{~V} ; \mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, unless otherwise noted.

Table 1.

| Parameter | Min | Typ | Max | Unit | Test Conditions/Comments |
| :---: | :---: | :---: | :---: | :---: | :---: |

## AD9552

| Parameter | Min | Typ | Max | Unit | Test Conditions/Comments |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Input Capacitance |  | 3 |  | pF |  |
| Input Resistance |  | 130 |  | $\mathrm{k} \Omega$ |  |
| Duty Cycle | 40 |  | 60 | \% |  |
| Input Voltage |  |  |  |  |  |
| Input High Voltage, $\mathrm{V}_{\mathrm{H}}$ | 0.52 |  |  | V |  |
| Input Low Voltage, V VIL |  |  | 1.62 | V |  |
| Input Threshold Voltage |  | 1.0 |  | V | When ac coupling to the input receiver, the user must dc bias the input to 1 V |
| VCO CHARACTERISTICS |  |  |  |  |  |
| Frequency Range |  |  |  |  |  |
| Upper Bound |  | 4050 |  | MHz |  |
| Lower Bound |  | 3350 |  | MHz |  |
| VCO Gain |  | 45 |  | MHz/V |  |
| VCO Tracking Range | $\pm 300$ |  |  | ppm |  |
| VCO Calibration Time |  | 140 |  |  | $\mathrm{f}_{\mathrm{PFD}}{ }^{7}=77.76 \mathrm{MHz}$; time between completion of the VCO calibration command (the rising edge of $\overline{C S}$ (Pin 12)) to the rising edge of LOCKED (Pin 20). |

${ }^{1}$ The $\mathrm{A}[2: 0], \mathrm{Y}[5: 0]$, and OUTSEL pins have $100 \mathrm{k} \Omega$ internal pull-up resistors.
${ }^{2}$ The RESET pin has a $100 \mathrm{k} \Omega$ internal pull-up resistor, so the default state of the device is reset.
${ }^{3} \mathrm{~N}$ is the integer part of the feedback divider.
${ }^{4}$ Sigma-delta modulator.
${ }^{5}$ The minimum allowable feedback divider value with the SDM disabled.
${ }^{6}$ The minimum allowable feedback divider value with the SDM enabled.
${ }^{7}$ The frequency at the input to the phase-frequency detector.

## CRYSTAL INPUT CHARACTERISTICS

Table 2.

| Parameter | Min | Typ | Max | Unit | Test Conditions/Comments |
| :--- | :--- | :--- | :--- | :--- | :--- |
| CRYSTAL FREQUENCY |  |  |  |  |  |
| $\quad$ Range | 10 | 26 | 52 | MHz |  |
| $\quad$ Tolerance |  |  | 20 | ppm |  |
| CRYSTAL MOTIONAL RESISTANCE |  | 100 | $\Omega$ |  |  |
| CRYSTAL LOAD CAPACITANCE |  | 15 | pF | Using a crystal with a specified load capacitance other than <br> $15 \mathrm{pF}(8 \mathrm{pF}$ to 24 pF$)$ is possible, but necessitates using the <br> SPI port to configure the AD9552 crystal input capacitance. |  |

## OUTPUT CHARACTERISTICS

Table 3.

## SERIAL CONTROL PORT TIMING

Table 6.

| Parameter | Limit | Unit |
| :---: | :---: | :---: |
| SCLK |  |  |
| Clock Rate, 1/tclk | 50 | MHz max |
| Pulse Width High, $\mathrm{tHIGH}^{\text {l }}$ | 3 | ns min |
| Pulse Width Low, tıow | 3 | ns min |
| SDIO to SCLK Setup, tos | 4 | ns min |
| SCLK to SDIO Hold, $\mathrm{t}_{\text {oh }}$ | 0 | ns min |
| SCLK to Valid SDIO, tov | 13 | $n \mathrm{nsmax}$ |
| $\overline{\mathrm{CS}}$ to SCLK Setup ( $\mathrm{ts}_{\text {s }}$ and Hold ( $\mathrm{t}_{\mathrm{H}}$ ) | 0 | ns min |
| $\overline{\mathrm{CS}}$ Minimum Pulse Width High | 6.4 | $n s$ min |

## ABSOLUTE MAXIMUM RATINGS

Table 7.

| Parameter | Rating |
| :--- | :--- |
| Supply Voltage (VDD) | 3.6 V |
| Maximum Digital Input Voltage | -0.5 V to VDD +0.5 V |
| Storage Temperature | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Operating Temperature Range | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| Lead Temperature (Soldering, 10 sec$)$ | $300^{\circ} \mathrm{C}$ |
| Junction Temperature | $150^{\circ} \mathrm{C}$ |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## AD9552

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 2. Pin Configuration
Table 8. Pin Function Descriptions

| Pin No. | Mnemonic | Type ${ }^{1}$ | Description |
| :---: | :---: | :---: | :---: |
| $\begin{aligned} & 29,30,31, \\ & 32,1,2 \end{aligned}$ | $\begin{aligned} & \text { Y0, Y1, Y2, Y3, Y4, } \\ & \text { Y5 } \end{aligned}$ | I | Control Pins. These pins select preset values for the PLL feedback divider and the OUT1 dividers based on the input reference frequency selected via the $\mathrm{A}[0: 2]$ pins and have internal $100 \mathrm{k} \Omega$ pull-up resistors. |
| 3,4,5 | A0, A1, A2 | 1 | Control Pins. These pins select the input reference frequency and have internal $100 \mathrm{k} \Omega$ pullup resistors. |
| 6 | RESET | 1 | Digital Input, Active High. Resets internal logic to default states. This pin has an internal $100 \mathrm{k} \Omega$ pull-up resistor, so the default state of the device is reset. |
| 7, 18, 21, 28 | VDD | P | Power Supply Connection: 3.3 V Analog Supply. |
| 8, 17, 19 | LDO | P/O | LDO Decoupling Pins. Connect a $0.47 \mu \mathrm{~F}$ decoupling capacitor from each of these pins to ground. |
| 9, 10 | XTAL | 1 | Crystal Resonator Input. Connect a crystal resonator across these pins. |
| 11 | REF | 1 | Reference Clock Input. Connect this pin to an active clock input signal, or connect it to VDD when using a crystal resonator across the XTAL pins. |
| 12 | $\overline{\mathrm{CS}}$ | 1 | Digital Input, Active Low, Chip Select. |
| 13 | SCLK | 1 | Serial Data Clock. |
| 14 | SDIO | I/O | Digital Serial Data Input/Output. |
| 15 | OUTSEL | I | Logic 0 selects LVDS and Logic 1 selects LVPECL-compatible levels for both OUT1 and OUT2 when the outputs are not under SPI port control. Can be overridden via the programming registers. This pin has an internal $100 \mathrm{k} \Omega$ pull-up resistor. |
| 16 | FILTER | I/O | Loop Filter Node for the PLL. Connect an external 12 nF capacitor from this pin to Pin 17 (LDO). |
| 20 | LOCKED | O | Active High Locked Status Indicator for the PLL. |
| 26, 22 | $\overline{\text { OUT1, }}$ OUT2 | O | Complementary Square Wave Clocking Outputs. |
| 27, 23 | OUT1, OUT2 | O | Square Wave Clocking Outputs. |
| 24, 25 | GND | P | Analog Ground. |
| EP | Exposed Die Pad |  | The exposed die pad must be connected to GND. |

## THEORY OF OPERATION

Figure 19. Detailed Block Diagram

## PRESET FREQUENCY RATIOS

The frequency selection pins (A[2:0] and $\mathrm{Y}[5: 0]$ ) allow the user to hardwire the device for preset input and output divider values based on the pin logic states (see Figure 19). The pins decode ground or open connections as Logic 0 or Logic 1, respectively. Use the serial I/O port to change the divider values from the preset values provided by the $\mathrm{A}[2: 0]$ and $\mathrm{Y}[5: 0]$ pins.
The $\mathrm{A}[2: 0]$ pins select one of eight input reference frequencies (see Table 9). The user supplies the input reference frequency by connecting a single-ended clock signal to the REF pin or a crystal resonator across the XTAL pins. If the A[2:0] pins select 10 MHz , $12 \mathrm{MHz}, 12.8 \mathrm{MHz}$, or 16 MHz , the input frequency to the AD9552 doubles internally. Alternatively, if Register $0 \times 1 \mathrm{D}[2]$ is set to 1 , the input frequency doubles.

Table 9. Input Reference Frequency Selection Pins

| A2 | A1 | A0 | Reference Frequency (MHz) |
| :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 10.00 |
| 0 | 0 | 1 | 12.00 |
| 0 | 1 | 0 | 12.80 |
| 0 | 1 | 1 | 16.00 |
| 1 | 0 | 0 | 19.20 |
| 1 | 0 | 1 | 19.44 |
| 1 | 1 | 0 | 20.00 |
| 1 | 1 | 1 | 26.00 |

The $\mathrm{Y}[5: 0]$ pins select the appropriate feedback and output dividers to synthesize the output frequencies (see Table 10). The output frequencies provided in Table 10 are exact; that is, the number of decimal places displayed is sufficient to maintain full precision. Where a decimal representation is not practical, a fractional multiplier is used.

The VCO and output frequency shift in frequency by a ratio of the reference frequency used vs. the frequency specified in Table 9. Note that the VCO frequency must stay within the minimum and maximum range specified in Table 1. Typically, the selection of the VCO frequency band, as well as the gain adjustment, by the external pin strap occurs as part of the device's automatic VCO calibration process, which initiates at power up (or reset). If the user changes the VCO frequency band via the SPI interface, however, a forced VCO calibration should be initiated by first enabling SPI control of the VCO calibration (Register 0x0E[2] = 1) and then writing a 1 to the calibrate VCO bit (Register 0x0E[7]).

## AD9552

Table 10. Output Frequency Selection Pins

| Y5 | Y4 | Y3 | Y2 | Y1 | Y0 | VCO Frequency (MHz) | Output (MHz) |

## COMPONENT BLOCKS

## Input Reference

The AD9552 offers the following input reference options:

- Crystal resonator connected directly across the XTAL pins
- CMOS-compatible, single-ended clock source connected directly to the REF pin

In the case of a crystal resonator, the AD9552 expects a crystal with a specified load capacitance of 15 pF (default). The AD9552 provides the load capacitance internally. The internal load capacitance consists of a fixed component of 13 pF and a variable (programmable) component of 0 pF to 15.75 pF .
After applying power to the AD9552 (or after a device reset), the programmable component assumes a value of 2 pF . This establishes the default load capacitance of 15 pF .
To accommodate crystals with a specified load capacitance other than 15 pF ( 8 pF to 23.75 pF ), the user can adjust the programmable capacitance in 0.25 pF increments via Register 0x1B[5:0]. Note that when the user sets Register 0x1B[7] to 0 (enabling SPI control of the XTAL tuning capacitors), the variable capacitance changes from 2 pF (its power-up value) to 15.75 pF due to the default value of Register $0 \times 1 \mathrm{~B}[5: 0]$. This causes the crystal load capacitance to be 23.75 pF until the user overwrites the default contents of Register 0x1B[5:0].
A noncomprehensive, alphabetical list of crystal manufacturers includes the following:

- AVX/Kyocera
- ECS
- Epson Toyocom
- Fox Electronics
- NDK
- Siward

The AD9552 evaluation board functions with the NDK NX3225SA crystal or with the Siward 571200-A258-001 crystal. Although these crystals meet the load capacitance and motional resistance requirements of the AD9552 according to their data sheets, Analog Devices, Inc., does not guarantee their operation with the AD9552, nor does Analog Devices endorse one supplier of crystals over another.

## Reference Monitor

The REF input includes a monitor circuit that detects signal presence at the REF input. If the device detects a clock signal on the REF pin, it automatically selects the REF input as the input reference source and shuts down the crystal oscillator. This automatic preference for a REF input signal is the default mode of operation. However, the user can override the default setting via Register 0x1D[0]. Setting this bit forces the device to override the signal detector associated with the REF input and activates the crystal oscillator (whether or not a REF input signal is present).

## $\mathbf{2 \times}$ Frequency Multiplier

The $2 \times$ frequency multiplier provides the option to double the frequency delivered by either the REF or XTAL input. This allows the user to take advantage of a higher frequency delivered to the PLL, which allows for greater separation between the frequency generated by the PLL and the associated reference spur. However, increased reference spur separation comes at the expense of the harmonic spurs introduced by the frequency multiplier. As such, beneficial use of the frequency multiplier is application specific.

## PLL

The PLL consists of a phase/frequency detector (PFD), a partially integrated analog loop filter (see Figure 20), an integrated voltage-controlled oscillator (VCO), and a feedback divider with an optional third-order SDM that allows for fractional divide ratios. The PLL produces a nominal 3.7 GHz signal that is phase-locked to the input reference signal.
The loop bandwidth of the PLL is nominally 50 kHz . The PFD of the PLL drives a charge pump that automatically changes current proportionately to the feedback divider value. This increase or decrease in current maintains a constant loop bandwidth with changes in the input reference or the output frequency.

Figure 20. Internal Loop Filter

## AD9552

The gain of the PLL is proportional to the current delivered by the charge pump. The user can override the default charge pump current setting, and, thereby, the PLL gain, by using Register 0x0A[7:0].
The PLL has a VCO with 128 frequency bands spanning a range of 3350 MHz to 4050 MHz ( 3700 MHz nominal). However, the actual operating frequency within a particular band depends on the control voltage that appears on the loop filter capacitor. The control voltage causes the VCO output frequency to vary linearly within the selected band. This frequency variability allows the control loop of the PLL to synchronize the VCO output signal with the reference signal applied to the PFD. Typically, selection of the VCO frequency band (as well as gain adjustment) occurs automatically as part of the device's automatic VCO calibration process, which initiates at power up (or reset). Alternatively, the user can force VCO calibration by first enabling SPI control of VCO calibration (Register 0x0E[2] =1) and then writing a 1 to the calibrate VCO bit (Register 0x0E[7]). To facilitate system debugging, the user can override the VCO band setting by first enabling SPI control of VCO band (Register $0 \times 0 \mathrm{E}[0]=1$ ) and then writing the desired value to Register $0 \times 10[7: 1]$.

The PLL has a feedback divider coupled with a third-order SDM that enables the PLL to provide integer-plus-fractional frequency upconversion. The integer factor, N , is variable via an 8-bit programming register. The range of N is from $\mathrm{N}_{\text {MIN }}$ to 255 , where $\mathrm{N}_{\text {MIN }}$ is 36 or 47 depending on whether the SDM is disabled or enabled, respectively. The SDM in the feedback path allows for a fractional divide value that takes the form of $\mathrm{N}+$ $\mathrm{F} / \mathrm{M}$, where N is the integer part (eight bits), M is the modulus (20 bits), and F is the fractional part ( 20 bits), with all three parameters being positive integers.

The feedback SDM gives the AD9552 the ability to support a wide range of output frequencies with exact frequency ratios relative to the input reference.

## PLL Locked Indicator

The PLL provides a status indicator that appears at an external pin (LOCKED). The indicator shows when the PLL has acquired a locked condition.

## Output Dividers

Two integer dividers exist in the output chain. The first divider ( $\mathrm{P}_{0}$ ) yields an integer submultiple of the VCO frequency. The second divider ( $\mathrm{P}_{1}$ ) establishes the frequency at OUT1 as an integer submultiple of the output frequency of the $\mathrm{P}_{0}$ divider.

## Input-to-OUT2 Option

By default, OUT2 delivers an output frequency that is the same frequency as OUT1. However, the user has the option of making OUT2 a replica of the input frequency (REF or XTAL) by programming Register 33[3] $=1$.

## Output Drivers

The user has control over the following output driver parameters via the programming registers:

- Logic family and pin functionality
- Polarity (for CMOS family only)
- Drive current
- Power-down

The logic families are LVDS, LVPECL, and CMOS. Selection of the logic family is via the mode control bits in the OUT1 driver control register (Register 0x32[5:3]) and the OUT2 driver control register (Register 0x34[5:3]), as detailed in Table 11. Regardless of the selected logic family, each output driver uses two pins: OUT1 and $\overline{\text { OUT1 }}$ are used by one driver, and OUT2 and OUT2 are used by the other. This enables support of the differential signals associated with the LVDS and LVPECL logic families. CMOS, on the other hand, is a single-ended signal requiring only one output pin, but both output pins are available for optional provision of a dual, single-ended CMOS output clock. Refer to the first entry (CMOS (both pins)) in Table 11.

Table 11. Output Channel Logic Family and Pin Functionality

| Mode <br> Control Bits[2:0] | Logic Family and Pin Functionality |
| :--- | :--- |
| 000 | CMOS (both pins) |
| 001 | CMOS (positive pin), tristate (negative pin) |
| 010 | Tristate (positive pin), CMOS (negative pin) |
| 011 | Tristate (both pins) |
| 100 | LVDS |
| 101 | LVPECL |
| 110 | Undefined |
| 111 | Undefined |

If the mode bits indicate the CMOS logic family, the user has control of the logic polarity associated with each CMOS output pin via the OUT1 and OUT2 driver control registers.
If the mode bits indicate the CMOS or LVDS logic family, the user can select whether the output driver uses weak or strong drive capability via the OUT1 and OUT2 driver control registers. In the case of the CMOS family, the strong setting allows for driving increased capacitive loads. In the case of the LVDS family, the nominal weak and strong drive currents are 3.5 mA and 7 mA , respectively.
The OUT1 and OUT2 driver control registers also have a powerdown bit to enable/disable the output drivers. The power-down function is independent of the logic family selection.

Note that, unless the user programs the device to allow SPI port control of the output drivers, the drivers default to LVPECL or LVDS, depending on the logic level on the OUTSEL pin (Pin 15). For OUTSEL $=0$, both outputs are LVDS. For OUTSEL $=1$, both outputs are LVPECL. In the pin-selected LVDS mode, the user can still control the drive strength, using the SPI port.

## PART INITIALIZATION AND AUTOMATIC POWERON RESET

The AD9552 has an internal power-on reset circuit. At power-up, internal logic relies on the internal reference monitor to select either the crystal oscillator or the reference input and then initiates VCO calibration using whichever is found. If both are present, the external reference path is chosen.

VCO calibration is required in order for the device to lock. If the input reference signal is not present, VCO calibration waits until a valid input reference is present. As soon as an input reference signal is present, VCO calibration starts.
If the user wishes to use the crystal oscillator input even if the reference input is present, the user needs to set Bit 0 (use crystal resonator) in Register 0x1D.

Any change to the preset frequency selection pins or the PLL divide ratios requires the user to recalibrate the VCO.

## OUTPUT/INPUT FREQUENCY RELATIONSHIP

The frequency at OUT1 and OUT2 is a function of the PLL feedback divider values ( $\mathrm{N}, ~ \mathrm{FRAC}$, and MOD) and the output divider values ( $\mathrm{P}_{0}$ and $\mathrm{P}_{1}$ ). The equations that define the frequency at OUT1 and OUT2 (fout1 and fout2, respectively) are as follows.

$$
\begin{aligned}
& f_{\text {OUT } 1}=f_{\text {REF }}\left(K \times \frac{N+\frac{F R A C}{M O D}}{P_{0} P_{1}}\right) \\
& f_{\text {OUT } 2}=f_{\text {OUT } 1}
\end{aligned}
$$

where:
$f_{\text {REF }}$ is the input reference or crystal resonator frequency.
$K$ is the input mode scale factor.
$N$ is the integer feedback divider value.
$F R A C$ and $M O D$ are the fractional feedback divider values.
$P_{0}$ and $P_{1}$ are the OUT1 divider values.
The numerator of the fourl equation contains the feedback division factor, which has an integer part $(\mathrm{N})$ due to an integer divider along with an optional fractional part (FRAC/MOD) associated with the feedback SDM.

The following constraints apply:

$$
\begin{aligned}
& N_{M I N} \in\{36,47\} \\
& N \in\left\{N_{M I N}, N_{M I N}+1, \cdots, 255\right\} \\
& F R A C \in\{0,1, \cdots, 1,048,575\} \\
& M O D \in\{1,2, \cdots, 1,048,575\} \\
& K \in\{1,2\} \\
& P_{0} \in\{4,5, \cdots, 11\} \\
& P_{1} \in\{1,2, \cdots, 63\}
\end{aligned}
$$

Note that $\mathrm{N}_{\mathrm{Min}}$ and K can each be one of two values. The value of $\mathrm{N}_{\text {Min }}$ depends on the state of the SDM. $\mathrm{N}_{\text {MIN }}=36$ when the SDM is disabled or $\mathrm{N}_{\text {MIN }}=47$ when it is enabled. The value of K depends on the $2 \times$ frequency multiplier. $K=1$ when the $2 \times$ frequency multiplier is bypassed, or $\mathrm{K}=2$ when it is enabled.

The frequency at the input to the PFD ( $\mathrm{f}_{\mathrm{PFD}}$ ) is calculated as follows:

$$
f_{P F D}=K \times f_{\text {REF }}
$$

The operating range of the $\mathrm{VCO}\left(3.35 \mathrm{GHz} \leq \mathrm{f}_{\mathrm{vco}} \leq 4.05 \mathrm{GHz}\right)$ places the following constraint on $f_{\text {PFD }}$ :

$$
\left(\frac{3350}{N+\frac{F R A C}{M O D}}\right) \mathrm{MHz} \leq f_{P F D} \leq\left(\frac{4050}{N+\frac{F R A C}{M O D}}\right) \mathrm{MHz}
$$

## CALCULATING DIVIDER VALUES

This section provides a three-step procedure for calculating the divider values when given a specific $\mathrm{f}_{\text {OUT }} / \mathrm{f}_{\text {REF }}$ ratio ( $\mathrm{f}_{\text {REF }}$ is the frequency of either the REF input signal source or the external crystal resonator). The computation process is described in general terms, but a specific example is provided for clarity. The example is based on a frequency control pin setting of $\mathrm{A}[2: 0]=111$ (see Table 9) and $\mathrm{Y}[5: 0]=101000$ (see Table 10), yielding the following:

$$
\begin{aligned}
& f_{\text {REF }}=26 \mathrm{MHz} \\
& f_{\text {outl }}=625 \times(66 / 64) \mathrm{MHz}
\end{aligned}
$$

1. Determine the output divide factor (ODF).

Note that the VCO frequency ( $\mathrm{f}_{\mathrm{vco}}$ ) spans 3350 MHz to 4050 MHz . The ratio, $\mathrm{f}_{\mathrm{vco}} / \mathrm{f}_{\text {outi }}$, indicates the required ODF. Given the specified value of fout1 $(\sim 644.53 \mathrm{MHz})$ and the range of $\mathrm{f}_{\mathrm{vco}}$, the ODF spans a range of 5.2 to 6.3. The ODF must be an integer, which means that $\mathrm{ODF}=6$ (because 6 is the only integer between 5.2 and 6.3).
2. Determine suitable values for $\mathrm{P}_{0}$ and $\mathrm{P}_{1}$.

The ODF is the product of the two output dividers, so $\mathrm{ODF}=\mathrm{P}_{0} \mathrm{P}_{1}$. It has already been determined that $\mathrm{ODF}=6$ for the given example. Therefore, $\mathrm{P}_{0} \mathrm{P}_{1}=6$ with the constraints that $P_{0}$ and $P_{1}$ are both integers and that $4 \leq P_{0} \leq 11$ (see the Output/Input Frequency Relationship section). These constraints lead to the single solution: $\mathrm{P}_{0}=6$ and $\mathrm{P}_{1}=1$.

Although this particular example yields a single solution for the output divider values with fout $\approx 644.53 \mathrm{MHz}$, some fouri frequencies result in multiple ODFs rather than just one. For example, if fout $=100 \mathrm{MHz}$ the ODF ranges from 34 to 40 . This leads to an assortment of possible values for P0 and P1, as shown in Table 12.

Table 12. Combinations for $P_{0}$ and $P_{1}$

| $\mathbf{P}_{\mathbf{0}}$ | $\mathbf{P}_{\mathbf{1}}$ | $\mathbf{O D F}\left(\mathbf{P}_{\mathbf{0}} \times \mathbf{P}_{\mathbf{1}}\right)$ |
| :--- | :--- | :--- |
| 4 | 9 | 36 |
| 4 | 10 | 40 |
| 5 | 7 | 35 |
| 5 | 8 | 40 |
| 6 | 6 | 36 |
| 7 | 5 | 35 |
| 8 | 5 | 40 |
| 9 | 4 | 36 |
| 10 | 4 | 40 |

## AD9552

The $P_{0}$ and $P_{1}$ combinations listed in Table 12 are all equally valid. However, note that they yield only three valid ODF values ( 35,36 , and 40 ) from the original range of 34 to 40 .
3. Determine the feedback divider values for the PLL.

Repeat this step for each ODF when multiple ODFs exist (for example, 35,36 , and 40 in the case of Table 12).
To calculate the feedback divider values for a given ODF, use the following equation:
$\left(\frac{f_{\text {OUT1 }}}{f_{\text {REF }}}\right) \times O D F=\frac{X}{Y}$
Note that the left side of the equation contains variables with known quantities. Furthermore, the values are necessarily rational, so the left side is expressible as a ratio of two integers, X and Y . Following is an example equation.
$\left(\frac{625\left[\frac{66}{64}\right]}{26}\right) \times 6=\frac{625(66)(6)}{26(64)}=\frac{247,500}{1664}=\frac{X}{Y}$
In the context of the AD9552, $\mathrm{X} / \mathrm{Y}$ is always an improper fraction. Therefore, it is expressible as the sum of an integer, N , and the proper fraction, $\mathrm{R} / \mathrm{Y}$ ( R and Y are integers).
$\frac{X}{Y}=N+\frac{R}{Y}$
$\frac{247,500}{1664}=N+\frac{R}{Y}$
This particular example yields $\mathrm{N}=148, \mathrm{Y}=1664$, and $\mathrm{R}=1228$. To arrive at this result, use long division to convert the improper fraction, $\mathrm{X} / \mathrm{Y}$, to an integer $(\mathrm{N})$ and a proper fraction ( $\mathrm{R} / \mathrm{Y}$ ). Note that dividing Y into X by means of long division yields an integer, N , and a remainder, R . The proper fraction has a numerator ( R , the remainder) and a denominator ( Y , the divisor), as shown in Figure 21.

$$
\frac{N}{Y \underset{\frac{N}{R}}{\frac{N Y}{R}}} \Rightarrow \frac{X}{Y}=N+\frac{R}{Y}
$$

Figure 21. Example Long Division
It is imperative that long division be used to obtain the correct results. Avoid the use of a calculator or math program, because these do not always yield correct results due to internal rounding and/or truncation. Some calculators or math programs may be up to the task if they can handle very large integer operations, but such are not common.

In the example, $\mathrm{N}=148$ and $\mathrm{R} / \mathrm{Y}=1228 / 1664$, which reduces to $\mathrm{R} / \mathrm{Y}=307 / 416$. These values of $\mathrm{N}, \mathrm{R}$, and Y constitute the following respective feedback divider values:
$\mathrm{N}=148, \mathrm{FRAC}=307$, and $\mathrm{MOD}=416$.
The only caveat is that N and MOD must meet the constraints given in the Output/Input Frequency Relationship section.
In the example, FRAC is nonzero, so the division value is an integer plus the fractional component, FRAC/MOD. This implies that the feedback SDM is necessary as part of the feedback divider. If FRAC $=0$, the feedback division factor is an integer and the SDM is not required (it can be bypassed).
Although the feedback divider values obtained in this way provide the proper feedback divide ratio to synthesize the exact output frequency, they may not yield optimal jitter performance at the final output. One reason for this is that the value of MOD defines the period of the SDM, which has a direct impact on the spurious output of the SDM. Specifically, in the spectral band from dc to $f_{\text {PFD }}$, the SDM exhibits spurs at intervals of $f_{\text {PPD }} /$ MOD. Thus, the spectral separation ( $\Delta \mathrm{f}$ ) of the spurs associated with the feedback SDM is

$$
\Delta f=\frac{f_{P F D}}{M O D}
$$

Because the SDM is in the feedback path of the PLL, these spurs appear in the output signal as spurious components offset by $\Delta \mathrm{f}$ from foutı. Therefore, a small MOD value pro-duces relatively large spurs with relatively large frequency offsets from fout1, whereas a large MOD value produces smaller spurs but more closely spaced to foutı. Clearly, the value of MOD has a direct impact on the spurious content (that is, jitter) at OUT1.

Generally, the largest possible MOD value yields the smallest spurs. Thus, it is desirable to scale MOD and FRAC by the integer part of $2^{20}$ divided by the value of MOD obtained previously. In the example, the value of MOD is 416, yield-ing a scale factor of 2520 (the integer part of 220/416). A scale factor of 2520 leads to FRAC $=307 \times 2520=773,640$ and MOD $=416 \times 2520=1,048,320$.

## LOW DROPOUT (LDO) REGULATORS

The AD9552 is powered from a single 3.3 V supply and contains on-chip LDO regulators for each function to eliminate the need for external LDOs. To ensure optimal performance, each LDO output should have a $0.47 \mu \mathrm{~F}$ capacitor connected between its access pin and ground, and this capacitor should be kept as close to the device as possible.

## APPLICATIONS INFORMATION

## THERMAL PERFORMANCE

Table 13. Thermal Parameters for the 32-Lead LFCSP Package

| Symbol | Thermal Characteristic Using a JEDEC51-7 Plus JEDEC51-5 2S2P Test Board ${ }^{1}$ | Value ${ }^{2}$ | Unit |
| :---: | :---: | :---: | :---: |
| $\theta_{\text {JA }}$ | Junction-to-ambient thermal resistance, $0.0 \mathrm{~m} / \mathrm{sec}$ airflow per JEDEC JESD51-2 (still air) | 40.5 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| $\theta_{\text {JMA }}$ | Junction-to-ambient thermal resistance, $1.0 \mathrm{~m} / \mathrm{sec}$ airflow per JEDEC JESD51-6 (moving air) | 35.4 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| $\theta_{\text {Jма }}$ | Junction-to-ambient thermal resistance, $2.5 \mathrm{~m} / \mathrm{sec}$ airflow per JEDEC JESD51-6 (moving air) | 31.8 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| $\theta_{\text {вв }}$ | Junction-to-board thermal resistance, $1.0 \mathrm{~m} / \mathrm{sec}$ airflow per JEDEC JESD51-8 (moving air) | 23.3 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| $\theta_{\text {¢ }}$ | Junction-to-case thermal resistance (die-to-heat sink) per MIL-Std 883, Method 1012.1 | 4.2 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| $\Psi_{\text {JT }}$ | Junction-to-top-of-package characterization parameter, $0 \mathrm{~m} / \mathrm{sec}$ airflow per JEDEC JESD51-2 (still air) | 0.4 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

${ }^{1}$ The exposed pad on the bottom of the package must be soldered to ground to achieve the specified thermal performance.
${ }^{2}$ Results are from simulations. The PCB is a JEDEC multilayer type. Thermal performance for actual applications requires careful inspection of the conditions in the application to determine whether they are similar to those assumed in these calculations.

The AD9552 is specified for a case temperature ( $\mathrm{T}_{\text {CASE }}$ ). To ensure that $\mathrm{T}_{\text {CASE }}$ is not exceeded, an airflow source can be used. Use the following equation to determine the junction temperature on the application PCB:

$$
T_{J}=T_{C A S E}+\left(\Psi_{J T} \times P_{D}\right)
$$

where:
$T_{J}$ is the junction temperature $\left({ }^{\circ} \mathrm{C}\right)$.
$T_{\text {CASE }}$ is the case temperature $\left({ }^{\circ} \mathrm{C}\right)$ measured by the customer at the top center of the package.
$\Psi_{J T}$ is the value indicated in Table 13.
$P_{D}$ is the power dissipation (see the Specifications section).

Values of $\theta_{\text {IA }}$ are provided for package comparison and PCB design considerations. $\theta_{\mathrm{JA}}$ can be used for a first-order approximation of $\mathrm{T}_{J}$ using the following equation:

$$
T_{J}=T_{A}+\left(\theta_{I A} \times P_{D}\right)
$$

where $T_{A}$ is the ambient temperature $\left({ }^{\circ} \mathrm{C}\right)$.
Values of $\theta_{\mathrm{JC}}$ are provided for package comparison and PCB design considerations when an external heat sink is required.

Values of $\theta_{\text {Jв }}$ are provided for package comparison and PCB design considerations.

## AD9552

## SERIAL CONTROL PORT

The AD9552 serial control port is a flexible, synchronous, serial communications port that allows an easy interface to many industry-standard microcontrollers and microprocessors. Single or multiple byte transfers are supported, as well as MSB first or LSB first transfer formats. The AD9552 serial control port is configured for a single bidirectional I/O pin (SDIO only).
The serial control port has two types of registers: read-only and buffered. Read-only registers are nonbuffered and ignore write commands. All writable registers are buffered (also referred to as mirrored) and require an I/O update to transfer the new values from a temporary buffer on the chip to the actual register. To invoke an I/O update, write a 1 to the I/O update bit found in Register 0x05[0]. Because any number of bytes of data can be changed before issuing an update command, the update simultaneously enables all register changes occurring since any previous update.

## SERIAL CONTROL PORT PIN DESCRIPTIONS

SCLK (serial data clock) is the serial shift clock. This pin is an input. SCLK is used to synchronize serial control port reads and writes. Write data bits are registered on the rising edge of this clock, and read data bits are registered on the falling edge. This pin is internally pulled down by a $30 \mathrm{k} \Omega$ resistor to ground.
SDIO (digital serial data input/output) is a dual-purpose pin that acts as input only or as an input/output. The AD9552 defaults to bidirectional pins for I/O.
$\overline{\mathrm{CS}}$ (chip select bar) is an active low control that gates the read and write cycles. When $\overline{\mathrm{CS}}$ is high, SDIO is in a high impedance state. This pin is internally pulled up by a $100 \mathrm{k} \Omega$ resistor to 3.3 V . It should not be left floating. See the Operation of the Serial Control Port section on the use of the $\overline{\mathrm{CS}}$ pin in a communication cycle.

Figure 22. Serial Control Port

## OPERATION OF THE SERIAL CONTROL PORT

## Framing a Communication Cycle with $\overline{C S}$

The $\overline{\mathrm{CS}}$ line gates the communication cycle (a write or a read operation). $\overline{\mathrm{CS}}$ must be brought low to initiate a communication cycle.
The $\overline{\mathrm{CS}}$ stall high function is supported in modes where three or fewer bytes of data (plus instruction data) are transferred. Bits[W1:W0] must be set to 00,01 , or 10 (see Table 14). In these modes, $\overline{\mathrm{CS}}$ may temporarily return high on any byte boundary, allowing time for the system controller to process the next byte. $\overline{\mathrm{CS}}$ can go high on byte boundaries only and can go high during either part (instruction or data) of the transfer. During this period,
the serial control port state machine enters a wait state until all data has been sent. If the system controller decides to abort before the complete transfer of all the data, the state machine must be reset either by completing the remaining transfer or by returning the $\overline{\mathrm{CS}}$ line low for at least one complete SCLK cycle (but fewer than eight SCLK cycles). A rising edge on the $\overline{\mathrm{CS}}$ pin on a nonbyte boundary terminates the serial transfer and flushes the buffer.

Table 14. Byte Transfer Count

| W1 | W0 | Bytes to Transfer <br> (Excluding the 2-Byte Instruction) |
| :--- | :--- | :--- |
| 0 | 0 | 1 |
| 0 | 1 | 2 |
| 1 | 0 | 3 |
| 1 | 1 | Streaming mode |

In the streaming mode (Bits[W1:W0] = 11), any number of data bytes can be transferred in a continuous stream. The register address is automatically incremented or decremented (see the MSB/LSB First Transfers section). $\overline{\mathrm{CS}}$ must be raised at the end of the last byte to be transferred, thereby ending the stream mode.

## Communication Cycle—Instruction Plus Data

There are two parts to a communication cycle with the AD9552. The first part writes a 16 -bit instruction word into the AD9552, coincident with the first 16 SCLK rising edges. The instruction word provides the AD9552 serial control port with information regarding the data transfer, which is the second part of the communication cycle. The instruction word defines whether the upcoming data transfer is a read or a write, the number of bytes in the data transfer, and the starting register address for the first byte of the data transfer.

## Write

If the instruction word is for a write operation (Bit I15 = 0), the second part is the transfer of data into the serial control port buffer of the AD9552. The length of the transfer (1,2, or 3 bytes; or streaming mode) is indicated by two bits (Bits[W1:W0]) in the instruction byte. The length of the transfer indicated by (Bits[W1:W0]) does not include the 2-byte instruction. $\overline{\mathrm{CS}}$ can be raised after each sequence of eight bits to stall the bus (except after the last byte, where it ends the cycle). When the bus is stalled, the serial transfer resumes when $\overline{\mathrm{CS}}$ is lowered. Stalling on nonbyte boundaries resets the serial control port.

## Read

If the instruction word is for a read operation (Bit $\mathrm{I} 15=1$ ), the next $\mathrm{N} \times 8$ SCLK cycles clock out the data from the address specified in the instruction word, where N is $1,2,3$, or 4 , as determined by Bits[W1:W0]. In this case, 4 is used for streaming mode, where four or more words are transferred per read. The data read back is valid on the falling edge of SCLK.

The default mode of the AD9552 serial control port is bidirectional mode, and the data read back appears on the SDIO pin.

By default, a read request reads the register value that is currently in use by the AD9552. However, setting Register 0x04[0] = 1 causes the buffered registers to be read instead. The buffered registers are the ones that take effect during the next I/O update.

Figure 23. Relationship Between the Serial Control Port Register Buffers and the Control Registers
The AD9552 uses Register 0x00 to Register 0x34. Although the AD9552 serial control port allows both 8-bit and 16-bit instructions, the 8-bit instruction mode provides access to five address bits (Address Bits[A4:A0]) only, which restricts its use to Address Space 0x00 to Address Space 0x01. The AD9552 defaults to 16-bit instruction mode on power-up, and the 8 -bit instruction mode is not supported.

## INSTRUCTION WORD (16 BITS)

The MSB of the instruction word (see Table 15) is $R / \bar{W}$, which indicates whether the instruction is a read or a write. The next two bits, W1 and W0, are the transfer length in bytes. The final 13 bits are the address bits (Address Bits[A12:A0]) at which the read or write operation is to begin.

For a write, the instruction word is followed by the number of bytes of data indicated by Bits[W1:W0], which is interpreted according to Table 14.
Address Bits[A12:A0] select the address within the register map that is written to or read from during the data transfer portion of the communication cycle. The AD9552 uses all of the 13-bit address space. For multibyte transfers, this address is the starting byte address.

## MSB/LSB FIRST TRANSFERS

The AD9552 instruction word and byte data can be MSB first or LSB first. The default for the AD9552 is MSB first. The LSB first mode can be set by writing a 1 to Register $0 x 00[6]$ and requires that an I/O update be executed. Immediately after the LSB first bit is set, all serial control port operations are changed to LSB first order.
When MSB first mode is active, the instruction and data bytes must be written from MSB to LSB. Multibyte data transfers in MSB first format start with an instruction byte that includes the register address of the most significant data byte. Subsequent data bytes must follow in order from high address to low address. In MSB first mode, the serial control port internal address generator decrements for each data byte of the multibyte transfer cycle.

When LSB first = 1 (LSB first), the instruction and data bytes must be written from LSB to MSB. Multibyte data transfers in LSB first format start with an instruction byte that includes the register address of the least significant data byte followed by multiple data bytes. The serial control port internal byte address generator increments for each data byte of the multibyte transfer cycle.
The AD9552 serial control port register address decrements from the register address just written toward $0 \times 00$ for multibyte I/O operations if the MSB first mode is active (default). If the LSB first mode is active, the serial control port register address increments from the address just written toward 0x34 for multibyte I/O operations.
Unused addresses are not skipped during multibyte I/O operations. The user should write the default value to a reserved register and should write only zeros to unmapped registers. Note that it is more efficient to issue a new write command than to write the default value to more than two consecutive reserved (or unmapped) registers.

Table 15. Serial Control Port, 16-Bit Instruction Word, MSB First MSB

| I 15 | I 14 | I 13 | I 12 | I 11 | I 10 | I 9 | I 8 | I 7 | I 6 | I 5 | I 4 | I 3 | I 2 | I 1 | I 0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

Table 16. Definition of Terms Used in Serial Control Port Timing Diagrams

| Parameter | Description |
| :--- | :--- |
| $\mathrm{t}_{\mathrm{CLK}}$ | Period of SCLK |
| $\mathrm{t}_{\mathrm{DV}}$ | Read data valid time (time from falling edge of SCLK to valid data on SDIO) |
| $\mathrm{t}_{\mathrm{DS}}$ | Setup time between data and rising edge of SCLK |
| $\mathrm{t}_{\mathrm{DH}}$ | Hold time between data and rising edge of SCLK |
| $\mathrm{t}_{\mathrm{S}}$ | Setup time between $\overline{\mathrm{CS}}$ and SCLK |
| $\mathrm{t}_{\mathrm{H}}$ | Hold time between $\overline{\mathrm{CS}}$ and SCLK |
| $\mathrm{t}_{\text {HIGH }}$ | Minimum period that SCLK should be in a logic high state |
| $\mathrm{t}_{\text {LOw }}$ | Minimum period that SCLK should be in a logic low state |

## REGISTER MAP

A bit that is labeled "aclr" is an active high, autoclearing bit. When set to a Logic 1 state, the control logic automatically returns it to a Logic 0 state upon completion of the indicated task.

Table 17. Register Map

| Addr. <br> (Hex) | Register Name | (MSB) Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | $\begin{aligned} & \hline \text { (LSB) } \\ & \text { Bit } 0 \\ & \hline \end{aligned}$ | Default |

## REGISTER MAP DESCRIPTIONS

Control bit functions are active high unless stated otherwise. Register address values are always hexadecimal unless otherwise indicated.

## Serial Port Control (Register 0x00 to Register 0x05)

Table 18.

| Address | Bit | Bit Name | Description |
| :--- | :--- | :--- | :--- |
| $0 \times 00$ | 7 | Unused | Forced to Logic 0 internally, which enables 3-wire mode only. |
|  | 6 | LSB first | Bit order for SPI port. <br> $0=$ most significant bit and byte first (default). <br> $1=$ least significant bit and byte first. |
|  | 5 | Soft reset | Software initiated reset (register values set to default). This is an autoclearing bit. |
|  | 4 | Unused | Forced to Logic 1 internally, which enables 16 -bit mode (the only mode supported by <br> the device). |
|  | $[3: 0]$ | Unused | Mirrored version of the contents of Register 0x00[7:4] (that is, Bits[3:0] = Bits[7:4]). |
| $0 \times 04$ | $[7: 1]$ | Unused | Unused. |
|  | 0 | Readback control | For buffered registers, serial port readback reads from actual (active) registers instead of <br> from the buffer. <br> $0=$ reads values currently applied to the internal logic of the device (default). <br> $1=$ reads buffered values that take effect on next assertion of I/O update. |
|  | $[7: 1]$ | Unused | Unused. |
|  | 0 | I/O update | Writing a 1 to this bit transfers the data in the serial I/O buffer registers to the internal <br> control registers of the device. This is an autoclearing bit. |

## PLL Charge Pump and PFD Control (Register 0x0A to Register 0x0D)

Table 19.

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x0A | [7:0] | Charge pump current control | These bits set the magnitude of the PLL charge pump current. The granularity is $\sim 3.5 \mu \mathrm{~A}$ with a full-scale magnitude of $\sim 900 \mu \mathrm{~A}$. Register $0 \times 0 \mathrm{~A}$ is ineffective unless Register $0 \times 0 \mathrm{~B}[7]=1$. Default is $0 \times 80$, or $\sim 448 \mu \mathrm{~A}$. |
| 0x0B | 7 | Enable SPI control of charge pump current | Controls functionality of Register 0x0A. <br> $0=$ the device automatically controls the charge pump current (default). <br> 1 = charge pump current defined by Register 0x0A. |
|  | 6 | Enable SPI control of antibacklash period | Controls functionality of Register 0x0D[7:6]. <br> $0=$ the device automatically controls the antibacklash period (default). <br> 1 = antibacklash period defined by Register 0x0D[7:6]. |
|  | [5:4] | CP mode | Controls the mode of the PLL charge pump. $00=$ tristate. <br> 01 = pump up. <br> 10 = pump down. <br> 11 = normal (default). |
|  | 3 | Enable CP mode control | Controls functionality of Bits[5:4] (CP mode). <br> $0=$ the device automatically controls the charge pump mode (default). <br> 1 = charge pump mode is defined by Bits[5:4]. |
|  | 2 | PFD feedback input edge control | Selects the polarity of the active edge of the PLL's feedback input. $0=$ positive edge (default). <br> 1 = negative edge. |
|  | 1 | PFD reference input edge control | Selects the polarity of the active edge of the PLL's reference input. $0=$ positive edge (default). <br> 1 = negative edge. |
|  | 0 | Force VCO to midpoint frequency | Selects VCO control voltage functionality. $0=$ normal VCO operation (default). <br> 1 = force VCO control voltage to midscale. |
| 0x0C | 7 | Unused | Unused. |
|  | 6 | CP offset current polarity | Selects the polarity of the charge pump offset current of the PLL. This bit is ineffective unless Bit $3=1$. <br> $0=$ pump up (default). <br> 1 = pump down. |
|  | [5:4] | CP offset current | Controls the magnitude of the charge pump offset current of the PLL as a fraction of the value in Register 0x0A. This bit is ineffective unless Bit $3=1$. $\begin{aligned} & 00=1 / 2 \text { (default). } \\ & 01=1 / 4 . \\ & 10=1 / 8 . \\ & 11=1 / 16 . \end{aligned}$ |
|  | 3 | Enable CP offset current control | $\begin{aligned} & \text { Controls functionality of Bits[6:4]. } \\ & 0=\text { the device automatically controls charge pump offset current (default). } \\ & 1=\text { charge pump offset current defined by Bits[6:4]. } \end{aligned}$ |
|  | 2:0 | Reserved |  |
| 0x0D | [7:6] | Antibacklash control | Controls the PFD antibacklash period of the PLL. These bits are ineffective unless Register 0x0B[6] = 1 . <br> $00=$ minimum (default). $01 \text { = low. }$ $10 \text { = high. }$ <br> 11 = maximum. |
|  | [5:1] | Unused | Unused. |
|  | 0 | PLL lock detector power-down | Controls power-down of the PLL lock detector. <br> $0=$ lock detector active (default). <br> 1 = lock detector powered down. |

## AD9552

## VCO Control (Register 0x0E to Register 0x10)

Table 20.

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x0E | 7 | Calibrate VCO | Initiates VCO calibration (this is an autoclearing bit). This bit is ineffective unless Bit $2=1$. |
|  | 6 | Enable ALC | Enables automatic level control (ALC) of the VCO. <br> $0=$ Register 0x0F[7:2] defines the VCO level. <br> 1 = the device automatically controls the VCO level (default). |
|  | [5:3] | ALC threshold | Controls the VCO ALC threshold detector level from minimum (000) to maximum (111). <br> The default is 110 . |
|  | 2 | Enable SPI control of VCO calibration | Enables functionality of Bit 7. <br> $0=$ the device automatically performs VCO calibration (default). <br> 1 = Bit 7 controls VCO calibration. |
|  | 1 | Boost VCO supply | Selects VCO supply voltage. <br> $0=$ normal supply voltage (default). <br> 1 = increase supply voltage by 100 mV . |
|  | 0 | Enable SPI control of VCO band setting | $\begin{aligned} & \text { Controls VCO band setting functionality. } \\ & 0=\text { the device automatically selects the VCO band (default). } \\ & 1=\text { VCO band defined by Register } 0 \times 10[7: 1] . \end{aligned}$ |
| 0x0F | [7:2] | VCO level control | Controls the VCO amplitude from minimum (00 0000) to maximum (11 1111). The default is 100000 . <br> These bits are ineffective unless $0 \times 0 \mathrm{E}[6]=0$. |
|  | [1:0] | Unused | Unused. |
| 0x10 | [7:1] | VCO band control | Controls the VCO frequency band from minimum (000 0000) to maximum (111 1111). The default is 1000000. |
|  | 0 | Unused | Unused. |

## PLL Control (Register 0x11 to Register 0x19)

Table 21.

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x11 | [7:0] | N | The 8-bit integer divide value for the SDM. Default is $0 \times 00$. Note that operational limitations impose a lower boundary of 64 ( $0 \times 40$ ) on N . |
| 0x12 | [7:0] | MOD | Bits[19:12] of the 20-bit modulus of the SDM. |
| 0x13 | [7:0] | MOD | Bits[11:4] of the 20-bit modulus of the SDM. |
| 0x14 | [7:4] | MOD | Bits[3:0] of the 20-bit modulus of the SDM. <br> Default is MOD $=10000000000000000000(524,288)$. |
|  | 3 | Enable SPI control of output frequency | Controls output frequency functionality. <br> $0=$ output frequency defined by the $\mathrm{Y}[3: 0]$ pins (default). <br> 1 = contents of Register $0 \times 11$ to Register 0x17 define output frequency via N, MOD, and FRAC. |
|  | 2 | Bypass SDM | Controls bypassing of the SDM. <br> 0 = allow integer-plus-fractional division (default). <br> 1 = allow only integer division. |
|  | 1 | Disable SDM | Controls the SDM internal clocks. <br> $0=$ normal operation (SDM clocks active) (default). <br> 1 = SDM disabled (SDM clocks stopped). |
|  | 0 | Reset PLL | Controls initialization of the PLL. <br> $0=$ normal operation (default). <br> 1 = resets the counters and logic associated with the PLL but does not affect the output dividers. |
| 0x15 | [7:0] | FRAC | Bits[19:12] of the 20-bit fractional part of the SDM. |
| 0x16 | [7:0] | FRAC | Bits[11:4] of the 20-bit fractional part of the SDM. |
| $0 \times 17$ | [7:4] | FRAC | Bits[3:0] of the 20-bit fractional part of the SDM. Default is FRAC $=00100000000000000000(131,072)$. |
|  | [3:1] | Unused | Write zeros to these bits when programming this register. |
|  | 0 | $\mathrm{P}_{1}$ divider | Bit 5 of the 6-bit $\mathrm{P}_{1}$ divider for OUT1. |

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x18 | [7:3] | $\mathrm{P}_{1}$ divider | Bits[4:0] of the 6-bit $\mathrm{P}_{1}$ divider for OUT1 ( $1 \leq \mathrm{P}_{1} \leq 63$ ). Do not set these bits to 000000 . Default is $P_{1}=100000$ (32). The $P_{1}$ bits are ineffective unless Register $0 \times 19[7]=1$. |
|  | [2:0] | $\mathrm{P}_{0}$ divider | The 3-bit $P_{0}$ divider for OUT1. The $P_{0}$ divide value is as follows: $\begin{aligned} & 000=4 \text { (default). } \\ & 001=5 . \\ & 010=6 . \\ & 011=7 . \\ & 100=8 . \\ & 101=9 . \\ & 110=10 . \\ & 111=11 . \end{aligned}$ <br> The $\mathrm{P}_{0}$ bits are ineffective unless Register $0 \times 19[7]=1$. |
| 0x19 | 7 | Enable SPI control of OUT1 dividers | Controls functionality of OUT1 dividers. <br> $0=$ OUT1 dividers defined by the $\mathrm{Y}[5: 0]$ pins (default). <br> 1 = contents of Register 0x17 and Register 0x18 define OUT1 dividers ( $\mathrm{P}_{0}$ and $\mathrm{P}_{1}$ ). |
|  | [6:0] | Unused | Unused. |

## Input Receiver and Band Gap Control (Register 0x1A)

Table 22.

| Address | Bit | Bit Name | Description |
| :--- | :--- | :--- | :--- |
| $0 \times 1 \mathrm{~A}$ | 7 | Receiver reset | Input receiver reset control. This is an autoclearing bit. <br> $0=$ normal operation (default). <br> $1=$ reset input receiver logic. |
|  |  |  | Controls the band gap voltage setting from minimum (0 0000) to maximum (1 1111). <br> Default is 00000. |
|  | [6:2] | Band gap voltage adjust | Unused. |
|  | 1 | Unused | Enables functionality of Bits[6:2]. <br>  <br>  |
|  | 0 | Enable SPI control of band gap |  |
|  | voltage |  | $1=$ Bits[6:2] define the receiver band gap voltage. |

## XTAL Control (Register 0x1B to Register 0x1D)

Table 23.

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x1B | 7 | Disable SPI control of XTAL tuning capacitance | Disables functionality of Bits[5:0]. <br> $0=$ tuning capacitance defined by Bits[5:0]. <br> $1=$ the device automatically selects XTAL tuning capacitance (default). |
|  | 6 | Unused | Unused. |
|  | [5:0] | XTAL tuning capacitor control | Capacitance value coded as inverted binary ( 0.25 pF per bit); that is, 111111 is 0 pF , 111110 is 0.25 pF , and so on. The default value, 000000 , is 15.75 pF . |
| 0x1C | [7:0] | Unused | Unused. |
| 0x1D | [7:3] | Unused | Unused. |
|  | 2 | Select $2 \times$ frequency multiplier | Select/bypass the $2 \times$ frequency multiplier. $0=$ bypassed (default). <br> 1 = selected. |
|  | 1 | Unused | Unused. |
|  | 0 | Use crystal resonator | Automatic external reference select override. <br> $0=$ the device automatically selects the external reference path if an external reference signal is present (default). <br> $1=$ the device uses the crystal resonator input whether or not an external reference signal is present. |

## AD9552

## OUT1 Driver Control (Register 0x32)

Table 24.

| Address | Bit | Bit Name | Description |
| :--- | :--- | :--- | :--- |
| $0 \times 32$ | 7 | OUT1 drive strength | Controls the output drive capability of the OUT1 driver. <br> $0=$ weak. |
|  |  |  | $1=$ strong (default). |$.$| Controls power-down functionality of the OUT1 driver. |
| :--- |
|  |

## Select OUT2 Source Control (Register 0x33)

Table 25.

| Address | Bit | Bit Name | Description |
| :--- | :--- | :--- | :--- |
| $0 \times 33$ | $[7: 4]$ | Unused | Unused. |
|  | 3 | OUT2 source | Selects the signal source for OUT2. <br> $0=$ source for OUT2 is the output of the $P_{1}$ divider (default). <br>  |
|  |  | $1=$ source for OUT2 is the input reference (REF or XTAL). |  |
|  | $[2: 0]$ | Unused | Unused. |

## OUT2 Driver Control (Register 0x34)

Table 26.

| Address | Bit | Bit Name | Description |
| :--- | :--- | :--- | :--- |
| $0 \times 34$ | 7 | OUT2 drive strength | Controls the output drive capability of the OUT2 driver. <br> $0=$ weak. <br>  |
|  |  |  | $1=$ strong (default). |$.$| Controls power-down functionality of the OUT2 driver. |
| :--- |
|  |
|  |
|  |

## AD9552

## OUTLINE DIMENSIONS

| ORDERING GUIDE | Temperature Range | Package Description | Package Option |
| :--- | :--- | :--- | :--- |
| Model $^{1}$ | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 32-Lead Lead Frame Chip Scale Package [LFCSP_VQ] | CP-32-2 |
| AD9552BCPZ | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 32-Lead Lead Frame Chip Scale Package [LFCSP_VQ] | CP-32-2 |
| AD9552BCPZ-REEL7 | Evaluation Board |  |  |
| AD9552/PCBZ |  |  |  |
