

Isolated, Precision Half-Bridge Driver, 0.1 A Output

ADuM1233

FEATURES

Isolated high-side and low-side outputs

High side or low side relative to input: $\pm 700 V_{PEAK}$

High side/low side differential: $700 V_{PEAK}$

0.1 A peak output current

High frequency operation: 5 MHz maximum

High common-mode transient immunity: $>75 \text{ kV}/\mu\text{s}$

High temperature operation: 105°C

Wide body, 16-lead SOIC

UL1577 2500 V rms input-to-output withstand voltage

APPLICATIONS

Isolated IGBT/MOSFET gate drives

Plasma displays

Industrial inverters

Switching power supplies

GENERAL DESCRIPTION

The ADuM1233¹ is an isolated, half-bridge gate driver that employs the Analog Devices, Inc. *iCoupler*[®] technology to provide independent and isolated high-side and low-side outputs. Combining high speed CMOS and monolithic transformer technology, this isolation component provides outstanding performance characteristics superior to optocoupler-based solutions.

By avoiding the use of LEDs and photodiodes, this *iCoupler* gate drive device is able to provide precision timing characteristics not possible with optocouplers. Furthermore, the reliability and performance stability problems associated with optocoupler LEDs are avoided.

In comparison to gate drivers employing high voltage level translation methodologies, the ADuM1233 offers the benefit of true, galvanic isolation between the input and each output. Each output can be operated up to $\pm 700 V_{PEAK}$ relative to the input, thereby supporting low-side switching to negative voltages. The differential voltage between the high side and low side can be as high as $700 V_{PEAK}$.

As a result, the ADuM1233 provides reliable control over the switching characteristics of IGBT/MOSFET configurations over a wide range of positive or negative switching voltages.

ELECTRICAL CHARACTERISTICS

All voltages are relative to their respective ground. $4.5\text{ V} \leq V_{DD1} \leq 5.5\text{ V}$, $12\text{ V} \leq V_{DDA} \leq 18\text{ V}$, $12\text{ V} \leq V_{DDB} \leq 18\text{ V}$. All min/max specifications apply over the entire recommended operating range, unless otherwise noted. All typical specifications are at $T_A = 25^\circ\text{C}$, $V_{DD1} = 5\text{ V}$, $V_{DDA} = 15\text{ V}$, $V_{DDB} = 15\text{ V}$.

¹ Short-circuit duration less than 1 second.

² The minimum pulse width is the shortest pulse width at which the specified timing parameters are guaranteed.

³ The maximum switching frequency is the maximum signal frequency at which the specified timing parameters are guaranteed.

⁴ t_{PHL} propagation delay is measured from the 50% level of the falling edge of the V_{ix} signal to the 50% level of the falling edge of the V_{Ox} signal. t_{PLH} propagation delay is measured from the 50% level of the rising edge of the V_{ix} signal to the 50% level of the rising edge of the V_{Ox} signal.

⁵ Channel-to-channel matching, rising or falling edges is the magnitude of the propagation delay difference between two channels of the same part when the inputs are either both rising or falling edges. The supply voltages and the loads on each channel are equal.

⁶ Channel-to-channel matching, rising vs. falling edges is the magnitude of the propagation delay difference between two channels of the same part when one input is a rising edge and the other input is a falling edge. The supply voltages and loads on each channel are equal.

⁷ Part-to-part matching, rising or falling edges is the magnitude of the propagation delay difference between the same channels of two different parts when the inputs are either both rising or falling edges. The supply voltages, temperatures, and loads of each part are equal.

⁸ Part-to-part matching, rising vs. falling edges is the magnitude of the propagation delay difference between the same channels of two different parts when one input is a rising edge and the other input is a falling edge. The supply voltages, temperatures, and loads of each part are equal.

⁴ Refers to common-mode transients across any insulation barrier. Common-mode transients exceeding the Absolute Maximum Ratings may cause latch-up or permanent damage.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device.

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

APPLICATION NOTES

COMMON-MODE TRANSIENT IMMUNITY

In general, common-mode transients consist of linear and sinusoidal components. The linear component of a common-mode transient is given by

$$V_{CM, linear} = (\Delta V / \Delta t) t$$

where $\Delta V / \Delta t$ is the slope of the transient shown in Figure 11 and Figure 12.

The transient of the linear component is given by

$$dV_{CM}/dt = \Delta V / \Delta t$$

The ability of the ADuM1233 to operate correctly in the presence of linear transients is characterized by the data in Figure 8. The data is based on design simulation and is the maximum linear transient magnitude that the ADuM1233 can tolerate without an operational error. This data shows a higher level of robustness than what is listed in Table 5 because the transient immunity values obtained in Table 5 use measured data and apply allowances for measurement error and margin.

Figure 8. Transient Immunity (Linear Transients) vs. Temperature

The sinusoidal component (at a given frequency) is given by

$$V_{CM, sinusoidal} = V_o \sin(2\pi ft)$$

where:

V_o is the magnitude of the sinusoidal.

f is the frequency of the sinusoidal.

The transient magnitude of the sinusoidal component is given by

$$dV_{CM}/dt = 2\pi f V_o.$$

The ability of the ADuM1233 to operate correctly in the presence of sinusoidal transients is characterized by the data in Figure 9 and Figure 10. The data is based on design simulation and is the maximum sinusoidal transient magnitude ($2\pi f V_o$) that the ADuM1233 can tolerate without an operational error. Values for immunity against sinusoidal transients are not included in Table 5 because measurements to obtain such values have not been possible.
