All Rights Reserved.

Attention please!

As far as patents or other rights of third parties are concerned, liability is only assumed for components, not for applications, processes and circuits implemented within components or assemblies.

The information describes the type of component and shall not be considered as assured characteristics.

Terms of delivery and rights to change design reserved.

For questions on technology, delivery and prices please contact the Semiconductor Group Offices in Germany or the Siemens Companies and Representatives worldwide (see address list).

Due to technical requirements components may contain dangerous substances. For information on the types in question please contact your nearest Siemens Office, Semiconductor Group.

Siemens AG is an approved CECC manufacturer.

Packing

Please use the recycling operators known to you. We can also help you – get in touch with your nearest sales office. By agreement we will take packing material back, if it is sorted. You must bear the costs of transport.

For packing material that is returned to us unsorted or which we are not obliged to accept, we shall have to invoice you for any costs incurred.

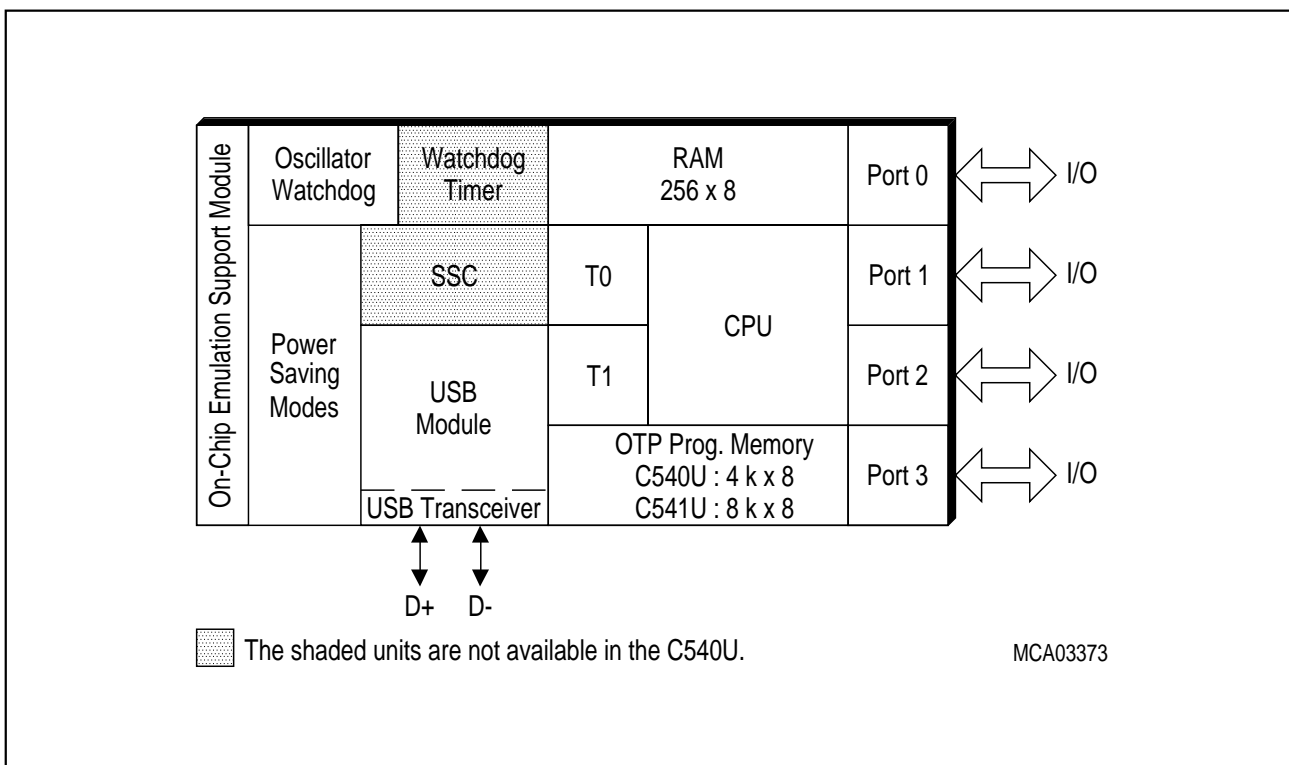

Components used in life-support devices or systems must be expressly authorized for such purpose!

Critical components¹ of the Semiconductor Group of Siemens AG, may only be used in life-support devices or systems² with the express written approval of the Semiconductor Group of Siemens AG.

- 1 A critical component is a component used in a life-support device or system whose failure can reasonably be expected to cause the failure of that life-support device or system, or to affect its safety or effectiveness of that device or system.
- 2 Life support devices or systems are intended (a) to be implanted in the human body, or (b) to support and/or maintain and sustain human life. If they fail, it is reasonable to assume that the health of the user may be endangered.

Advance Information

- Enhanced 8-bit C500 CPU
 - Full software/toolset compatible to standard 80C51/80C52 microcontrollers
- 12 MHz external operating frequency
 - 500 ns instruction cycle
- Built-in PLL for USB synchronization
- On-chip OTP program memory
 - C540U : 4K byte
 - C541U : 8K byte
 - Alternatively up to 64K byte external program memory
 - Optional memory protection
- On-chip USB module
 - Compliant to USB specification
 - Full speed or low speed operation
 - Five endpoints : one bidirectional control endpoint
four versatile programmable endpoints
 - Registers are located in special function register area
 - On-chip USB transceiver

Features (cont'd) :

- Up to 64K byte external data memory
- 256 byte on-chip RAM
- Four parallel I/O ports
 - P-LCC-44 package : three 8-bit ports and one 6-bit port
 - P-SDIP-52 package : four 8-bit ports
 - LED current drive capability for 3 pins (10 mA)
- Two 16-bit timer/counters (C501 compatible)
- SSC synchronous serial interface (SPI compatible) (only C541U)
 - Master and slave capable
 - Programmable clock polarity / clock-edge to data phase relation
 - LSB/MSB first selectable
 - 1.5 MBaud transfer rate at 12 MHz operating frequency
- 7 interrupt sources (2 external, 5 internal with 2 USB interrupts) selectable at 2 priority levels
- Enhanced fail safe mechanisms
 - Programmable watchdog timer (only C541U)
 - Oscillator watchdog
- Power saving modes
 - idle mode
 - software power down mode with wake-up capability through $\overline{\text{INT0}}$ pin or USB
- On-chip emulation support logic (Enhanced Hooks Technology™)
- P-LCC-44 and P-SDIP-52 packages
- Power supply voltage range : 4.0V to 5.5V
- Temperature Range :

SAB-C540U	$T_A = 0 \text{ to } 70 \text{ }^\circ\text{C}$
SAB-C541U	$T_A = 0 \text{ to } 70 \text{ }^\circ\text{C}$

Symbol	Pin Numbers		I/O*)	Function
	P-LCC-44	P-SDIP-52		
P0.0 - P0.7	44 - 36	50 - 43	I/O	Port 0 is an 8-bit open-drain bidirectional I/O port. Port 0 pins that have 1's written to them float, and in that state can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application it uses strong internal pullup resistors when issuing 1's.
V _{CCU}	1	1	–	Supply voltage for the on-chip USB transceiver circuitry.
V _{SSU}	2	2	–	Ground (0V) for the on-chip USB transceiver circuitry.
V _{CC}	8, 23	10, 26	–	Supply voltage for ports and internal logic circuitry during normal, idle, and power down mode.
V _{SS}	9, 22	11, 25	–	Ground (0V) for ports and internal logic circuitry during normal, idle, and power down mode.

*) I = Input
O = Output

Figure 5
Block Diagram of the C540U/C541U

CPU

The C540U/C541U is efficient both as a controller and as an arithmetic processor. It has extensive facilities for binary and BCD arithmetic and excels in its bit-handling capabilities. Efficient use of program memory results from an instruction set consisting of 44 % one-byte, 41 % two-byte, and 15% three- byte instructions. With a 12 MHz crystal, 58% of the instructions are executed in 500ns.

Special Function Register PSW (Address D0_H)

Reset Value : 00_H

Bit No.	MSB							LSB	
	D7 _H	D6 _H	D5 _H	D4 _H	D3 _H	D2 _H	D1 _H	D0 _H	
D0 _H	CY	AC	F0	RS1	RS0	OV	F1	P	PSW

Bit	Function															
CY	Carry Flag Used by arithmetic instruction.															
AC	Auxiliary Carry Flag Used by instructions which execute BCD operations.															
F0	General Purpose Flag															
RS1 RS0	Register Bank Select Control Bits These bits are used to select one of the four register banks. <table border="1" style="width: 100%; border-collapse: collapse; margin-top: 5px;"> <thead> <tr> <th style="text-align: center;">RS1</th> <th style="text-align: center;">RS0</th> <th style="text-align: left;">Function</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td>Bank 0 selected, data address 00_H-07_H</td> </tr> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> <td>Bank 1 selected, data address 08_H-0F_H</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td>Bank 2 selected, data address 10_H-17_H</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">1</td> <td>Bank 3 selected, data address 18_H-1F_H</td> </tr> </tbody> </table>	RS1	RS0	Function	0	0	Bank 0 selected, data address 00 _H -07 _H	0	1	Bank 1 selected, data address 08 _H -0F _H	1	0	Bank 2 selected, data address 10 _H -17 _H	1	1	Bank 3 selected, data address 18 _H -1F _H

0	0	Bank 0 selected, data address 00 _H -07 _H														
0	1	Bank 1 selected, data address 08 _H -0F _H														
1	0	Bank 2 selected, data address 10 _H -17 _H														
1	1	Bank 3 selected, data address 18 _H -1F _H														
OV	Overflow Flag Used by arithmetic instruction.															
F1	General Purpose Flag															
P	Parity Flag Set/cleared by hardware after each instruction to indicate an odd/even number of "one" bits in the accumulator, i.e. even parity.															

Memory Organization

The C540U/C541U CPU manipulates operands in the following four address spaces:

- 8 or 4 KByte on-chip OTP program memory
- Totally up to 64 Kbyte internal/external program memory
- up to 64 Kbyte of external data memory
- 256 bytes of internal data memory
- a 128 byte special function register area

Figure 6 illustrates the memory address spaces of the C540U/C541U.

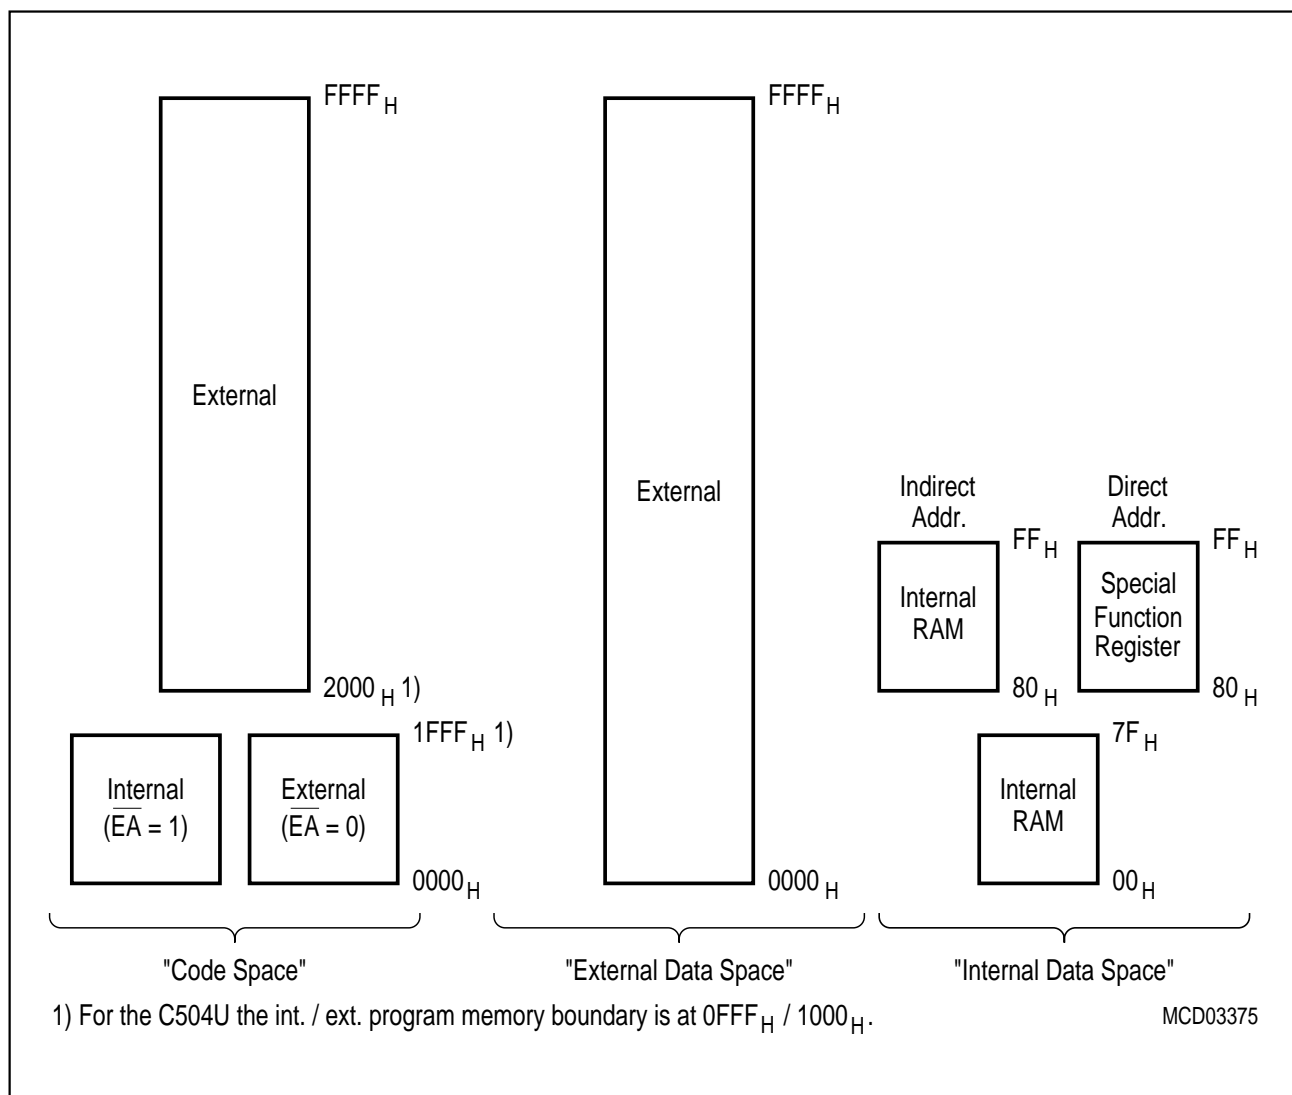

Figure 6
C540U/C541U Memory Map Memory Map

Reset and System Clock

The reset input is an active high input at pin RESET. Since the reset is synchronized internally, the RESET pin must be held high for at least two machine cycles (12 oscillator periods) while the oscillator is running. A pulldown resistor is internally connected to V_{SS} to allow a power-up reset with an external capacitor only. An automatic reset can be obtained when V_{CC} is applied by connecting the RESET pin to V_{CC} via a capacitor. **Figure 7** shows the possible reset circuitries.

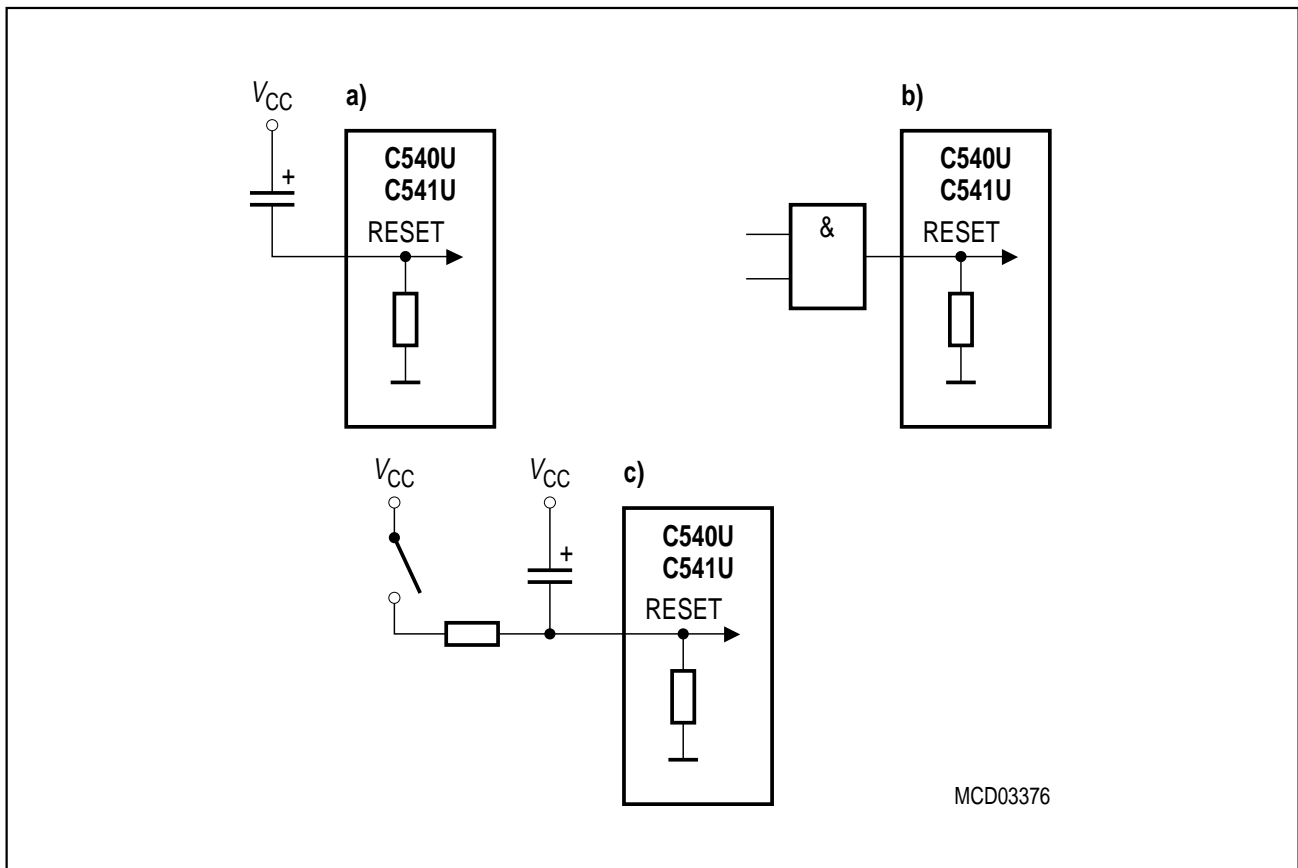

Figure 7
Reset Circuitries

The oscillator and clock generation circuitry of the C540U/C541U is shown in **figure 5-8**. The crystal oscillator generates the system clock for the microcontroller. The USB module can be provided with the following clocks :

- Full speed operation : 48 MHz with a data rate of 12 Mbit/s
- Low speed operation : 6 MHz with a data rate of 1.5 Mbit/s

The low speed clock is generated by a dividing the system clock by 2. The full speed clock is generated by a PLL, which multiplies the system clock by a fix factor of 4. This PLL can be enabled or disabled by bit PCLK of SFR DCR. Depending on full or low speed operation of the USB bit SPEED of SFR has to be set or cleared for the selection of the USB clock. Bit UCLK is a general enable bit for the USB clock.

Figure 8
Block Diagram of the Clock Generation Circuitry

The clock generator provides the internal clock signals to the chip. These signals define the internal phases, states and machine cycles. **Figure 9** shows the recommended oscillator circuits for crystal and external clock operation.

Figure 9
Recommended Oscillator Circuitries

Enhanced Hooks Emulation Concept

The Enhanced Hooks Emulation Concept of the C500 microcontroller family is a new, innovative way to control the execution of C500 MCUs and to gain extensive information on the internal operation of the controllers. Emulation of on-chip ROM based programs is possible, too.

Each production chip has built-in logic for the support of the Enhanced Hooks Emulation Concept. Therefore, no costly bond-out chips are necessary for emulation. This also ensures that emulation and production chips are identical.

The Enhanced Hooks Technology™¹⁾, which requires embedded logic in the C500 allows the C500 together with an EH-IC to function similar to a bond-out chip. This simplifies the design and reduces costs of an ICE-system. ICE-systems using an EH-IC and a compatible C500 are able to emulate all operating modes of the different versions of the C500 microcontrollers. This includes emulation of ROM, ROM with code rollover and ROMless modes of operation. It is also able to operate in single step mode and to read the SFRs after a break.

Figure 10
Basic C500 MCU Enhanced Hooks Concept Configuration

Port 0, port 2 and some of the control lines of the C500 based MCU are used by Enhanced Hooks Emulation Concept to control the operation of the device during emulation and to transfer informations about the programm execution and data transfer between the external emulation hardware (ICE-system) and the C500 MCU.

1 "Enhanced Hooks Technology" is a trademark and patent of Metalink Corporation licensed to Siemens.

Special Function Registers

The registers, except the program counter and the four general purpose register banks, reside in the special function register area. The special function register area consists of two portions: the standard special function register area and the mapped special function register area. One special function register of the C540U/C541U (PCON1) is located in the mapped special function register area. All other SFRs are located in the standard special function register area.

For accessing PCON1 in the mapped special function register area, bit RMAP in special function register SYSCON must be set.

Special Function Register SYSCON (Address B1_H)

Reset Value : XX10XXXX_B

The functions of the shaded bits are not described in this section.

Bit	Function
RMAP	<p>Special function register map bit</p> <p>RMAP = 0 : The access to the non-mapped (standard) special function register area is enabled.</p> <p>RMAP = 1 : The access to the mapped special function register area (PCON1) is enabled.</p>

As long as bit RMAP is set, a mapped special function register can be accessed. This bit is not cleared by hardware automatically. Thus, when non-mapped/mapped registers are to be accessed, the bit RMAP must be cleared/set by software, respectively each.

The registers, except the program counter and the four general purpose register banks, reside in the special function register area. All SFRs with addresses where address bits 0-2 are 0 (e.g. 80_H, 88_H, 90_H, 98_H, ..., F8_H, FF_H) are bitaddressable.

The 75 special function registers (SFRs) in the SFR area include pointers and registers that provide an interface between the CPU and the other on-chip peripherals. The SFRs of the C540U/C541U are listed in **table 3** to **table 4**. In **table 3** they are organized in groups which refer to the functional blocks of the C540U/C541U. **Table 4 and table 4** illustrate the contents of the SFRs in numeric order of their addresses.

Table 3
Special Function Registers - Functional Blocks

Block	Symbol	Name	Address	Contents after Reset
CPU	ACC	Accumulator	E0H ¹⁾	00H

Digital I/O Ports

The C540U/C541U in the P-SDIP-52 package has four 8-bit I/O ports. In the P-LCC-44 package port 1 is a 6-bit I/O port only. Port 0 is an open-drain bidirectional I/O port, while ports 1 to 3 are quasi-bidirectional I/O ports with internal pullup resistors. That means, when configured as inputs, ports 1 to 3 will be pulled high and will source current when externally pulled low. Port 0 will float when configured as input.

The output drivers of port 0 and 2 and the input buffers of port 0 are also used for accessing external memory. In this application, port 0 outputs the low byte of the external memory address, time multiplexed with the byte being written or read. Port 2 outputs the high byte of the external memory address when the address is 16 bits wide. Otherwise, the port 2 pins continue emitting the P2 SFR contents. In this function, port 0 is not an open-drain port, but uses a strong internal pullup FET.

Two port lines of port 1 (P1.0/LED0, P1.1/LED1) and one port line of port 3 (P3.0/LED2) have the capability of driving external LEDs in the output low state.

Timer / Counter 0 and 1

Timer/Counter 0 and 1 can be used in four operating modes as listed in **table 6** :

Table 6
Timer/Counter 0 and 1 Operating Modes

Mode	Description	TMOD		Input Clock	
		M1	M0	internal	external (max)
0	8-bit timer/counter with a divide-by-32 prescaler	0	0	$f_{osc}/6 \times 32$	$f_{osc}/12 \times 32$
1	16-bit timer/counter	1	1	$f_{osc}/6$	$f_{osc}/12$
2	8-bit timer/counter with 8-bit autoreload	1	0		
3	Timer/counter 0 used as one 8-bit timer/counter and one 8-bit timer Timer 1 stops	1	1		

In the “timer” function ($C/\bar{T} = '0'$) the register is incremented every machine cycle. Therefore the count rate is $f_{osc}/6$.

In the “counter” function the register is incremented in response to a 1-to-0 transition at its corresponding external input pin (P3.4/T0, P3.5/T1). Since it takes two machine cycles to detect a falling edge the max. count rate is $f_{osc}/12$. External inputs $\overline{INT0}$ and $\overline{INT1}$ (P3.2, P3.3) can be programmed to function as a gate to facilitate pulse width measurements. **Figure 11** illustrates the input clock logic.

Figure 11
Timer/Counter 0 and 1 Input Clock Logic

SSC Interface (C541U only)

The C541U microcontroller provides a Synchronous Serial Channel unit, the SSC. This interface is compatible to the popular SPI serial bus interface. **Figure 12** shows the block diagram of the SSC. The central element of the SSC is an 8-bit shift register. The input and the output of this shift register are each connected via a control logic to the pin P1.3 / SRI (SSC Receiver In) and P1.4 / STO (SSC Transmitter Out). This shift register can be written to (SFR STB) and can be read through the Receive Buffer Register SRB.

Figure 12
SSC Block Diagram

The SSC has implemented a clock control circuit, which can generate the clock via a baud rate generator in the master mode, or receive the transfer clock in the slave mode. The clock signal is fully programmable for clock polarity and phase. The pin used for the clock signal is P1.2 / SCLK. When operating in slave mode, a slave select input \bar{s} is provided which enables the SSC interface and also will control the transmitter output. The pin used for this is P1.5 / \overline{SLS} .

The SSC control block is responsible for controlling the different modes and operation of the SSC, checking the status, and generating the respective status and interrupt signals.

USB Module

The USB module in the C540U/C541U handles all transactions between the serial USB bus and the internal (parallel) bus of the microcontroller. The USB module includes several units which are required to support data handling with the USB bus : the on-chip USB bus transceiver, the USB memory with two pages of 128 bytes each, the memory management unit (MMU) for USB and CPU memory access control, the UDC device core for USB protocol handling, the microcontroller interface with the USB specific special function registers and the interrupt control logic. A clock generation unit provides the clock signal for the USB module for full speed and low speed USB operation. **Figure 13** shows the block diagram of the functional units of the USB module with their interfaces.

Figure 13
USB Module Block Diagram

USB Registers

Two different kinds of registers are implemented in the USB module. The global registers (GEPIR, EPSEL, ADROFF, USBVAL) describe the basic functionality of the complete USB module and can be accessed via unique SFR addresses. For reduction of the number of SFR addresses which are needed to control the USB module inside the C540U/C541U, device registers and endpoint registers are mapped into an SFR address block of seven SFR addresses (C1_H to C7_H). The endpoint specific functionality of the USB module is controlled via the device registers DCR, DPWDR, DIER, DIRR and the frame number registers. An endpoint register set is available for each endpoint (n=0..4) and describes the functionality of the selected endpoint. **Figure 14** explains the structure of the USB module registers.

Figure 14
Register Structure of the USB Module

Interrupt System

The C541U provides seven (C540U : six) interrupt sources with two priority levels. Five interrupts can be generated by the on-chip peripherals (timer 0, timer 1, SSC interface, and USB module), and two interrupts may be triggered externally (P3.2/ $\overline{\text{INT0}}$ and P3.3/ $\overline{\text{INT1}}$).

Figure 15 to 17 give a general overview of the interrupt sources and illustrate the request and control flags which are described in the next sections.

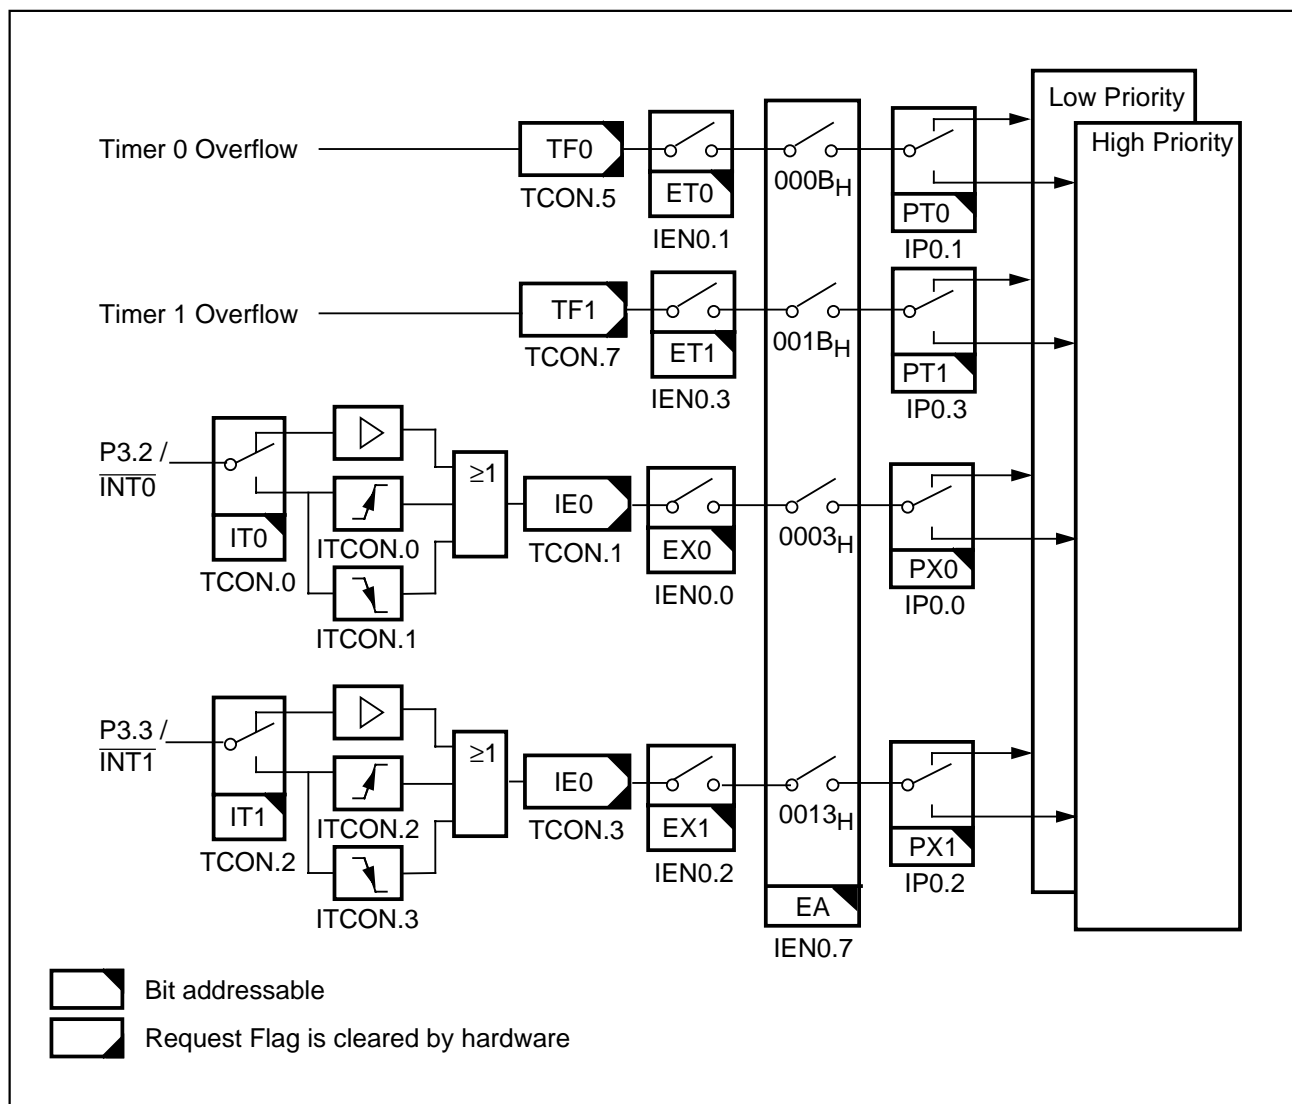

Figure 15
Interrupt Request Sources (Part 1)

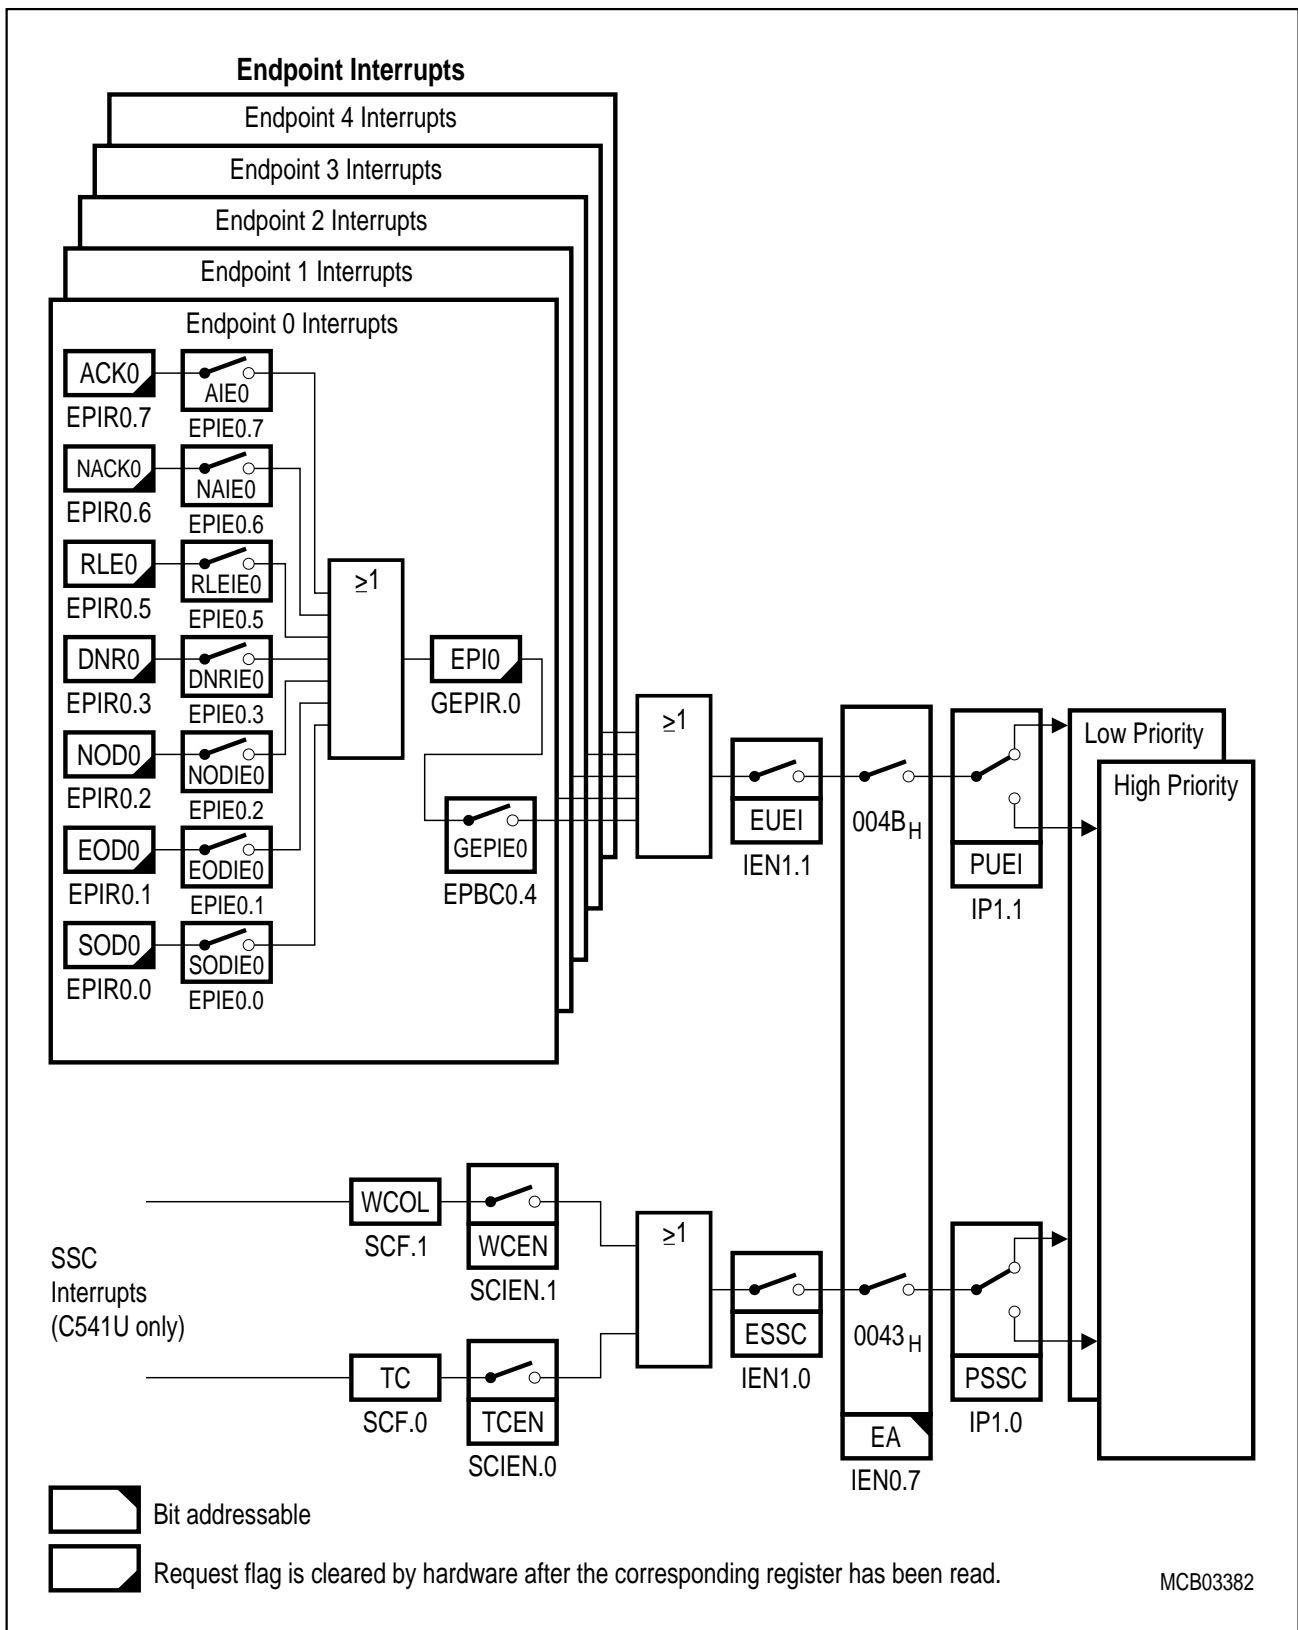

Figure 16
Interrupt Request Sources (Part 2)

Figure 17
Interrupt Request Sources (Part 3)

Table 7
Interrupt Source and Vectors

Interrupt Source	Interrupt Vector Address	Interrupt Request Flags (SFRs)
External Interrupt 0	0003 _H	IE0
Timer 0 Overflow	000B _H	TF0
External Interrupt 1	0013 _H	IE1
Timer 1 Overflow	001B _H	TF1
SSC Interrupt (C541U only)	0043 _H	TC, WCOL
USB Endpoint Interrupt	004B _H	in SFRs EPIR0-4 and GEIPR
USB Device Interrupt	0053 _H	in SFRs DIRR
Wake-up from power down	007B _H	–

Fail Save Mechanisms

The C540U/C541U offers enhanced fail safe mechanisms, which allow an automatic recovery from software upset or hardware failure :

- a programmable watchdog timer (WDT), with variable time-out period from 256 μ s up to approx. 0.55 μ s at 12 MHz. The WDT is not available in the C540U.
- an oscillator watchdog (OWD) which monitors the on-chip oscillator and forces the microcontroller into reset state in case the on-chip oscillator fails; it also provides the clock for a fast internal reset after power-on.

The watchdog timer in the C517A is a 15-bit timer, which is incremented by a count rate of $f_{osc}/12$ or $f_{osc}/192$. The system clock of the C517A is divided by two prescalers, a divide-by-two and a divide-by-16 prescaler which are selected by bit WDTSEL (WDTREL.7). For programming of the watchdog timer overflow rate, the upper 7 bit of the watchdog timer can be written. **Figure 8-18** shows the block diagram of the watchdog timer unit.

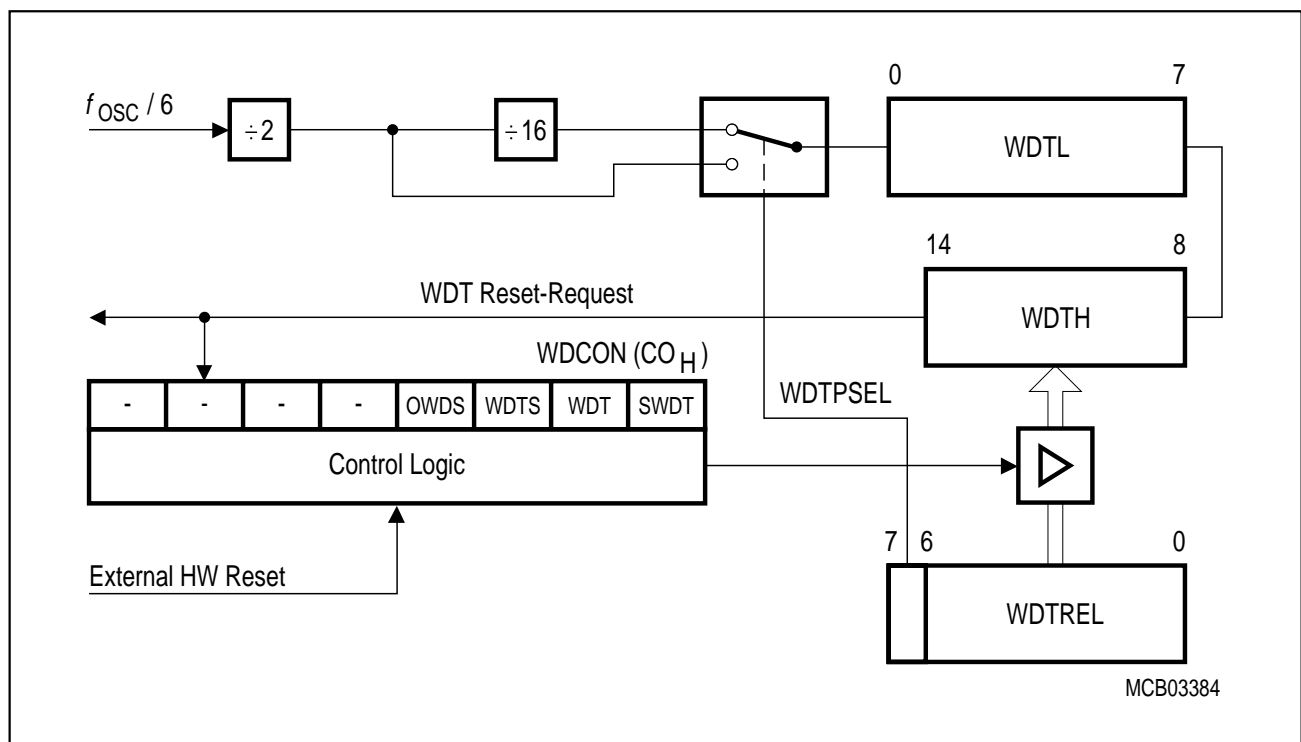

Figure 18
Block Diagram of the Watchdog Timer

The watchdog timer can be started by software (bit SWDT) but it cannot be stopped during active mode of the C541U. If the software fails to refresh the running watchdog timer an internal reset will be initiated on watchdog timer overflow. For refreshing of the watchdog timer the content of the SFR WDTREL is transferred to the upper 7-bit of the watchdog timer. The refresh sequence consists of two consecutive instructions which set the bits WDT and SWDT each. The reset cause (external reset or reset caused by the watchdog) can be examined by software (flag WDTS). It must be noted, however, that the watchdog timer is halted during the idle mode and power down mode of the processor.

Oscillator Watchdog

The oscillator watchdog unit serves for three functions:

- **Monitoring of the on-chip oscillator's function**
The watchdog supervises the on-chip oscillator's frequency; if it is lower than the frequency of the auxiliary RC oscillator in the watchdog unit, the internal clock is supplied by the RC oscillator and the device is brought into reset; if the failure condition disappears (i.e. the on-chip oscillator has a higher frequency than the RC oscillator), the part executes a final reset phase of typ. 1 ms in order to allow the oscillator to stabilize; then the oscillator watchdog reset is released and the part starts program execution again.
- **Fast internal reset after power-on**
The oscillator watchdog unit provides a clock supply for the reset before the on-chip oscillator has started. The oscillator watchdog unit also works identically to the monitoring function.
- **Control of external wake-up from software power-down mode** (description see chapter 9)
When the power-down mode is left by a low level at the $\overline{\text{INT0}}$ pin or by the USB, the oscillator watchdog unit assures that the microcontroller resumes operation (execution of the power-down wake-up interrupt) with the nominal clock rate. In the power-down mode the RC oscillator and the on-chip oscillator are stopped. Both oscillators are started again when power-down mode is released. When the on-chip oscillator has a higher frequency than the RC oscillator, the microcontroller starts operation after a final delay of typ. 1 ms in order to allow the on-chip oscillator to stabilize.

Figure 19
Functional Block Diagram of the Oscillator Watchdog

Power Saving Modes

The C540U/C541U provides two basic power saving modes, the idle mode and the power down mode.

– **Idle mode**

In the idle mode the main oscillator of the C540U/C541U continues to run, but the CPU is gated off from the clock signal. However, the interrupt system, the SSC (C541U only), the USB module, and the timers with the exception of the watchdog timer (C541U only) are further provided with the clock. The CPU status is preserved in its entirety : the stack pointer, program counter, program status word, accumulator, and all other registers maintain their data during idle mode. The idle mode can be terminated by activating any enabled interrupt. or by a hardware reset.

– **Power down mode**

In the power down mode, the RC oscillator and the on-chip oscillator which operates with the XTAL pins is stopped. Therefore, all functions of the microcontroller are stopped and only the contents of the on-chip RAM, XRAM and the SFR's are maintained. The power down mode can be left either by an active reset signal or by a low signal at the P3.2/ $\overline{\text{INT0}}$ pin or any activity on the USB bus. Using reset to leave power down mode puts the microcontroller with its SFRs into the reset state. Using the $\overline{\text{INT0}}$ pin or USB bus for power down mode exit maintains the state of the SFRs, which has been frozen when power down mode is entered.

In the power down mode of operation, V_{CC} can be reduced to minimize power consumption. It must be ensured, however, that V_{CC} is not reduced before the power down mode is invoked, and that V_{CC} is restored to its normal operating level, before the power down mode is terminated. **Table 8** gives a general overview of the entry and exit procedures of the power saving modes.

Table 8
Power Saving Modes Overview

Mode	Entering 2-Instruction Example	Leaving by	Remarks
Idle mode	ORL PCON, #01H ORL PCON, #20H	Ocurrence of an interrupt from a peripheral unit	CPU clock is stopped; CPU maintains their data; peripheral units are active (if enabled) and provided with clock
		Hardware Reset	
Power Down Mode	ORL PCON, #02H ORL PCON, #40H	Hardware Reset	Oscillator is stopped; contents of on-chip RAM and SFR's are maintained;
		Short low pulse at pin P3.2/ $\overline{\text{INT0}}$ or activity on the USB bus	

OTP Memory Operation

The C540U/C541U contains a 8k byte one-time programmable (OTP) program memory (C540U : 4k byte). With the C540U/C541U fast programming cycles are achieved (1 byte in 100 μ sec). Also several levels of OTP memory protection can be selected.

For programming of the device, the C540U/C541U must be put into the programming mode. This typically is done not in-system but in a special programming hardware. In the programming mode the C540U/C541U operates as a slave device similar as an EPROM standalone memory device and must be controlled with address/data information, control lines, and an external 11.5V programming voltage. **Figure 20** shows the pins of the C504-2E which are required for controlling of the OTP programming mode.

Figure 20
Programming Mode Configuration

Pin Configuration in Programming Mode

Read OTP version byte	V_{IH}	H		L	H	Byte addr. of sign. byte	D0-7

Lock Bits Programming / Read

The C540U/C541U has two programmable lock bits which, when programmed according **table 11**, provide four levels of protection for the on-chip OTP code memory. The state of the lock bits can also be read.

Table 11
Lock Bit Protection Types

Lock Bits at D1,D0		Protection Level	Protection Type
D1	D0		
1	1	Level 0	The OTP lock feature is disabled. During normal operation of the C540U/C541U, the state of the \overline{EA} pin is not latched on reset.
1	0	Level 1	During normal operation of the C540U/C541U, MOV _C instructions executed from external program memory are disabled from fetching code bytes from internal memory. \overline{EA} is sampled and latched on reset. An OTP memory read operation is only possible using the OTP verification mode for protection level 1. Further programming of the OTP memory is disabled (reprogramming security).
0	1	Level 2	Same as level 1, but also OTP memory read operation using OTP verification mode is disabled.
0	0	Level 3	Same as level 2; but additionally external code execution by setting \overline{EA} =low during normal operation of the C540U/C541U is no more possible. External code execution, which is initiated by an internal program (e.g. by an internal jump instruction above the ROM boundary), is still possible.

Absolute Maximum Ratings

Ambient temperature under bias (T_A)	0 to 70 °C
Storage temperature (T_{stg})	– 65 °C to 150 °C
Voltage on V_{CC} pins with respect to ground (V_{SS})	– 0.5 V to 6.5 V
Voltage on any pin with respect to ground (V_{SS})	– 0.5 V to $V_{CC} + 0.5$ V
Input current on any pin during overload condition	– 10 mA to 10 mA
Absolute sum of all input currents during overload condition	100 mA
Power dissipation	TBD

Note: Stresses above those listed under “Absolute Maximum Ratings” may cause permanent damage of the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for longer periods may affect device reliability. During overload conditions ($V_{IN} > V_{CC}$ or $V_{IN} < V_{SS}$) the Voltage on V_{CC} pins with respect to ground (V_{SS}) must not exceed the values defined by the absolute maximum ratings.

DC Characteristics

$V_{CC} = 4.0V$ to $5.5V$ ($5V +10\%$, -20%); $V_{SS} = 0 V$ $T_A = 0$ to $70\text{ }^\circ\text{C}$

Parameter	Symbol	Limit Values		Unit	Test Condition
		min.	max.		
Input low voltage (except \overline{EA} , RESET)	V_{IL}	- 0.5	$0.2 V_{CC} - 0.1$	V	-
Input low voltage (\overline{EA})	V_{IL1}	- 0.5	$0.2 V_{CC} - 0.3$	V	-
Input low voltage (RESET)	V_{IL2}	- 0.5	$0.2 V_{CC} + 0.1$	V	-

Output high voltage (port 0 in external bus mode, ALE, \overline{PSEN})	V_{OH2}	2.4 $0.9 V_{CC}$	- -	V	$I_{OH} = - 800\text{ }\mu\text{A}$ $I_{OH} = - 80\text{ }\mu\text{A}^2)$
Logic 0 input current (ports 1, 2, 3)	I_{IL}	- 10	- 50	μA	$V_{IN} = 0.45\text{ V}$
Logical 1-to-0 transition current (ports 1, 2, 3)	I_{TL}	- 65	- 650	μA	$V_{IN} = 2\text{ V}$
Input leakage current (port 0, \overline{EA})	I_{LI}	-	± 1	μA	$0.45 < V_{IN} < V_{CC}$
Pin capacitance	C_{IO}	-	10	pF	$f_c = 1\text{ MHz}$, $T_A = 25\text{ }^\circ\text{C}^7)$
Overload current	I_{OV}	-	± 5	mA	^{6) 7)}
Programming voltage	V_{PP}	10.9	12.1	V	$11.5\text{ V} \pm 5\%$

Notes see next page

Power Supply Current

Parameter		Symbol	Limit Values		Unit	Test Condition
			typ. ⁸⁾	max. ⁹⁾		
Active mode	12 MHz	I_{CC}	15	TBD	mA	⁴⁾
Idle mode	12 MHz	I_{CC}	TBD	TBD	mA	⁵⁾
Power-down mode		I_{PD}	TBD	50	μ A	$V_{CC} = 2 \dots 5.5 \text{ V}^{3)}$

Notes :

- 1) Capacitive loading on ports 0 and 2 may cause spurious noise pulses to be superimposed on the V_{OL} of ALE and port 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operation. In the worst case (capacitive loading > 100 pF), the noise pulse on ALE line may exceed 0.8 V. In such cases it may be desirable to qualify ALE with a schmitt-trigger, or use an address latch with a schmitt-trigger strobe input.
- 2) Capacitive loading on ports 0 and 2 may cause the V_{OH} on ALE and $\overline{\text{PSEN}}$ to momentarily fall below the 0.9 V_{CC} specification when the address lines are stabilizing.
- 3) I_{PD} (power-down mode) is measured under following conditions:
 $\overline{\text{EA}} = \text{Port 0} = V_{CC}$; XTAL2 = N.C.; XTAL1 = V_{SS} ; RESET = V_{SS} ; all other pins are disconnected.
 the USB transceiver is switched off;
- 4) I_{CC} (active mode) is measured with:
 XTAL1 driven with t_{CLCH} , $t_{CHCL} = 5 \text{ ns}$, $V_{IL} = V_{SS} + 0.5 \text{ V}$, $V_{IH} = V_{CC} - 0.5 \text{ V}$; XTAL2 = N.C.;
 $\overline{\text{EA}} = \text{RESET} = \text{Port 0} = \text{Port 1} = V_{CC}$; all other pins are disconnected.
 I_{CC} would be slightly higher if a crystal oscillator is used (appr. 1 mA).
- 5) I_{CC} (idle mode) is measured with all output pins disconnected and with all peripherals disabled;
 XTAL1 driven with t_{CLCH} , $t_{CHCL} = 5 \text{ ns}$, $V_{IL} = V_{SS} + 0.5 \text{ V}$, $V_{IH} = V_{CC} - 0.5 \text{ V}$; XTAL2 = N.C.;
 $\overline{\text{EA}} = \text{RESET} = V_{SS}$; Port 0 = V_{CC} ; all other pins are disconnected;
- 6) Overload conditions occur if the standard operating conditions are exceeded, ie. the voltage on any pin exceeds the specified range (i.e. $V_{OV} > V_{CC} + 0.5 \text{ V}$ or $V_{OV} < V_{SS} - 0.5 \text{ V}$). The supply voltage V_{CC} and V_{SS} must remain within the specified limits. The absolute sum of input currents on all port pins may not exceed 50 mA.
- 7) Not 100% tested, guaranteed by design characterization.
- 8) The typical I_{CC} values are periodically measured at $T_A = +25 \text{ }^\circ\text{C}$ but not 100% tested.
- 9) The maximum I_{CC} values are measured under worst case conditions ($T_A = 0 \text{ }^\circ\text{C}$ and $V_{CC} = 5.5 \text{ V}$)

AC Characteristics

$V_{CC} = 4.0V$ to $5.5V$ ($5V +10\%$, -20%); $V_{SS} = 0 V$ $T_A = 0$ to $70\text{ }^\circ\text{C}$

(C_L for port 0, ALE and $\overline{\text{PSEN}}$ outputs = 100 pF ; C_L for all other outputs = 80 pF)

Address float to $\overline{\text{PSEN}}$	t_{AZPL}	0	–	0	–	ns

*) Interfacing the C540U/C541U to devices with float times up to 28 ns is permissible. This limited bus contention will not cause any damage to port 0 drivers.

**) For correct function of the USB module the C540U/C541U must operate with 12 MHz external clock. The microcontroller (except the USB module) operates down to 2 MHz.
