

10-bit 33MSPS A/D Converter

Description

The CXA1844Q is a 10-bit 33MSPS 2-step parallel type A/D converter for video signal processing.

This A/D converter operates on $\pm 5V$ power supplies. The analog signal can be converted to the digital signal by using this IC in conjunction with the Sample-and-hold IC (CXA1843Q).

Features

- Maximum operating speed : 33MSPS (Min.)
- Resolution : 10-bit
- Low power dissipation : 320mW (Typ.)
- Wide-band analog input : 15MHz
- Low input capacitance : 50 pF (Typ.)
- Built-in digital correction
(Compensation within ± 16 LSB)
- TTL input (Except CLK which is ECL LIKE)
- TTL output
- Output code : binary/2S complement/
1S complement

Function

10-bit 33MSPS 2-step parallel type A/D converter

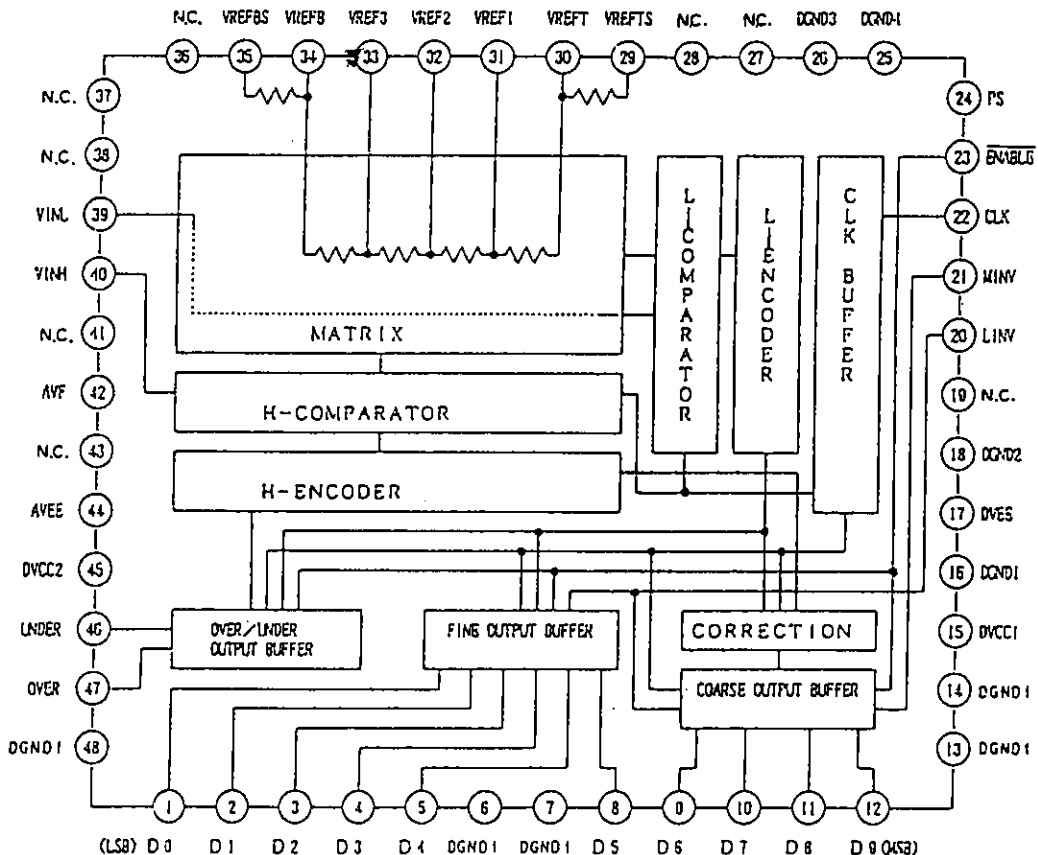

Structure

Bipolar silicon monolithic IC

Applications

High resolution video signal processing

Error Rate Test Circuit

Notes on Operation

1. Analog ground (Analog ground on PCB)
Keep analog ground surface on PCB as wide as possible with impedance and resistance as low as possible.
2. Digital ground (DGND1, DGND2, DGND3, DGND4)
Upon mounting to PCB keep ground surface as wide as possible with impedance and resistance as low as possible.
Moreover, a common analog and digital ground immediately near ADC will help obtain characteristics smoothly.
3. Digital positive power supply (DVcc1, DVcc2)
Connect to the digital ground with a ceramic capacitor over $0.1\ \mu\text{F}$ and as close to the pins as possible.
Insert a ceramic capacitor between DVcc2 and DGND1 of TTL output power supply as shortly as possible because noise tends to occur.
4. Analog positive power supply (AVF)
As shown in the Standard Circuit, make the positive power supply about $+0.7\text{V}$ by connecting to the analog ground with a diode and $+5\text{V}$ with a pull-up resistor respectively.
Connect to the analog ground on PCB with a ceramic capacitor over $0.1\ \mu\text{F}$ as close to the pin as possible.
5. Analog negative power supply (AV \bar{E})
Connect to the analog ground on PCB with a ceramic capacitor over $0.1\ \mu\text{F}$ as close to the pin as possible.
6. Digital negative power supply (DV \bar{E})
Connect to the digital ground with a ceramic capacitor over $0.1\ \mu\text{F}$ as close to the pin as possible.
When $V_{\bar{E}}$ is divided into digital and analog, there is continuity because of about $4\ \Omega$ resistance between the two inside the IC. Accordingly, if an excessive potential difference (more than 100mV) is applied continuously, this may destroy the IC. To prevent the IC destruction, connect AV \bar{E} and DV \bar{E} with a inductance having good high frequency characteristics. Prevent noise mixing and the generation of potential difference between analog and digital.
7. Reference voltage (VREFTS, VREFT, VREF1, VREF2, VREF3, VREFB, VREFBS)
These pins provide reference voltage to upper and lower comparators. Voltage between VREFT and VREFB corresponds to input dynamic range.
There is a $200\ \Omega$ resistance between VREFT and VREFB. By applying 2V to both pins a current of about $10\ \text{mA}$ flows. When the reference voltage is destabilized by the clock, ADC characteristics are adversely affected. Connect VREFT and VREFB to the analog ground on PCB by means of a tantalum capacitor over $10\ \mu\text{F}$ and a ceramic capacitor over $0.1\ \mu\text{F}$ respectively. Also, connect each of VREF1, VREF2 and VREF3 to the analog ground on PCB using a ceramic capacitor over $0.1\ \mu\text{F}$. This will provide stability to the characteristics of high frequency. Strictly speaking on reference voltage VREFT side and VREFB side there is a respective about 10mV offset.
When there is no problem with the usage of those offset voltages, voltage is applied directly to VREFT, VREFB. In case the reference voltage is to be strictly applied, adjust to obtain an offset voltage of 0V , keeping VREFTS and VREFBS as sense pins and VREFT and VREFB as force pins to form a feedback loop circuit. For details, see the Standard Circuit.

8. Analog input (VINH, VINL)
VINH is the input pin for the upper comparator while VINL is the input pin for the lower comparator.
Keep the input signal level within the level between VREFT and VREFB.
As this IC's analog input capacitance stands at about 50pF, it is necessary to drive with a buffer amplifier having sufficient driving capability. Also, when driving is done with the buffer amplifier of a low output impedance, as A/D converter input capacitance is large, ringing is generated and settling time grows longer. Here a small resistance of about 5 to 30Ω is connected in series between the buffer amplifier and each of A/D converter's VINH and VINL, as a dumping resistance. This eliminates ringing and shortens settling time. Also keep wiring between buffer amplifier and A/D converter as short as possible.
9. Clock input (CLK)
ECL LIKE input. Adds the signal of Vcc1 (5V) -0.8V at high level and Vcc1 (5V) -1.6V at low level. Clock line wiring should be the shortest possible while distanced from other signal lines to avoid affecting them.
This IC is 2-step parallel type A/D converter. Accordingly an external sample-and-hold circuit (SH) is necessary. However the timing between this SH circuit output waveform (A/D converter analog input waveform) and the A/D converter clock timing requires attention. In the relation between A/D converter clock and the A/D converter analog input signal, with the timing T_H of the rising edge of A/D converter clock, the upper comparator compares the input signal and the reference voltage to latch the results. After that, with the timing T_L of the falling edge of A/D converter clock, the lower comparator compares the input signal and reference signal to latch the results. (Strictly speaking, the sampling delay t_{SH} is in T_H and the sampling delay t_{SL} is in T_L .)
In this A/D converter, the lower comparator features a length of $\pm 32\text{mV}$ (± 16 LSB) redundancy in relation to the upper comparator. At the timing when the lower comparator compares input signal and reference signal to latch at the timing T_L , it is necessary to have the SH output settling performed. But at the timing when the upper comparator compares input signal and reference voltage to latch at the timing T_H , as long as the SH output is within the $\pm 32\text{mV}$ range to the final settling value, digital correction applies, A/D conversion precisely occurs. As seen from the above, A/D converter clock rise and fall timing versus SH output waveform should be duly considered. For the clock high level time t_{pWH} and low level time t_{pWL} , set to a value in excess of the time indicated for the respective operating conditions.
Output data is synchronously with the clock rising edge.
For details on timing, refer to the Timing Chart.
10. MINV input (MINV)
Digital output polarity inversion control pin of D9 (MSB).
TTL input. At open, turns to high level input.
For correspondence with analog input voltage and output data code, refer to the Output Formula Chart.
11. LINV input (LINV)
Digital output polarity inversion control pin of D8 to D0 (LSB).
TTL input. At open, turns to high level input.
For correspondence with analog input voltage and output data code, refer to the Output Formula Chart.
12. Output enable ($\overline{\text{ENABLE}}$)
3-state control pin of digital output (D0 to D9, UNDER, OVER)
TTL input. At open, turns to high level input. At that time digital output turns all to high impedance.
13. Power save input (PS)
Power save control pin of internal circuit.
TTL input. At open, turns to high level input.
To set to power save mode, turn both PS and $\overline{\text{ENABLE}}$ to high level input.

14. Digital output (D0 to D9)

Output pin of D9 (MSB) to D0 (LSB).

TTL output.

Output data polarity inversion is executed by means of MINV and LINV signals. Can output in binary, 1S complement and 2S complement.

Also, by turning $\overline{\text{ENABLE}}$ signal to high level, the output can be turned into high impedance output.

However, when the output level is for high impedance output or is in power save mode, the voltage of 3.6V or more must not be applied to prevent the destruction of IC.

For correspondence with analog input voltage and output data code, refer to the Output Formula Chart. For the timing, refer to the Timing Chart.

15. Overflow output (OVER)

When the input signal exceeds VREFT, overflow signal is output.

MINV and LINV have no effect on this pin.

Also by turning $\overline{\text{ENABLE}}$ signal to high level, the output can be turned into high impedance output.

However, when the output level is for high impedance output or is in power save mode, the voltage of 3.6V or more must not be applied to prevent the destruction of IC.

For correspondence with analog input voltage and output data code, refer to the Output Formula Chart.

For the timing, refer to the Timing Chart.

16. Underflow output (UNDER)

When the input signal turns below VREFB, underflow signal is output.

MINV and LINV have no effect on this pin.

Also by turning $\overline{\text{ENABLE}}$ signal to high level, the output can be turned into high impedance output.

However, when the output level is for high impedance output or is in power save mode, the voltage of 3.6V or more must not be applied to prevent the destruction of IC.

For correspondence with analog input voltage and output data code, refer to the Output Formula Chart.

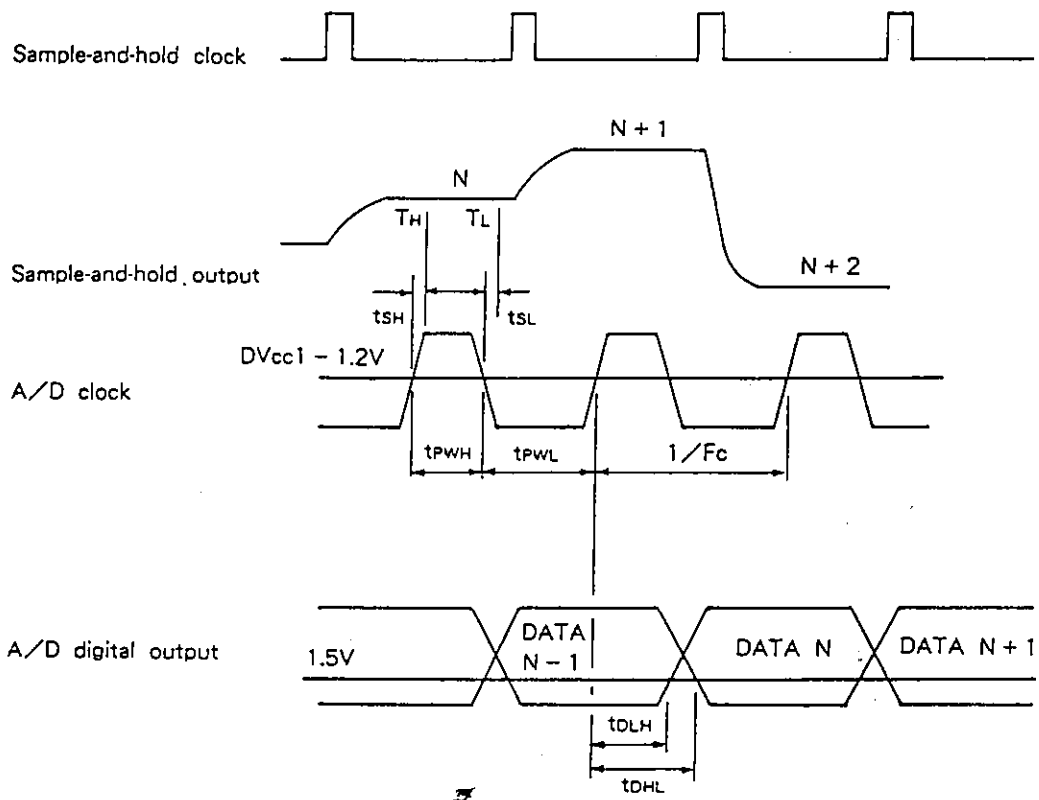

For the timing, refer to the Timing Chart.
