Functional Description

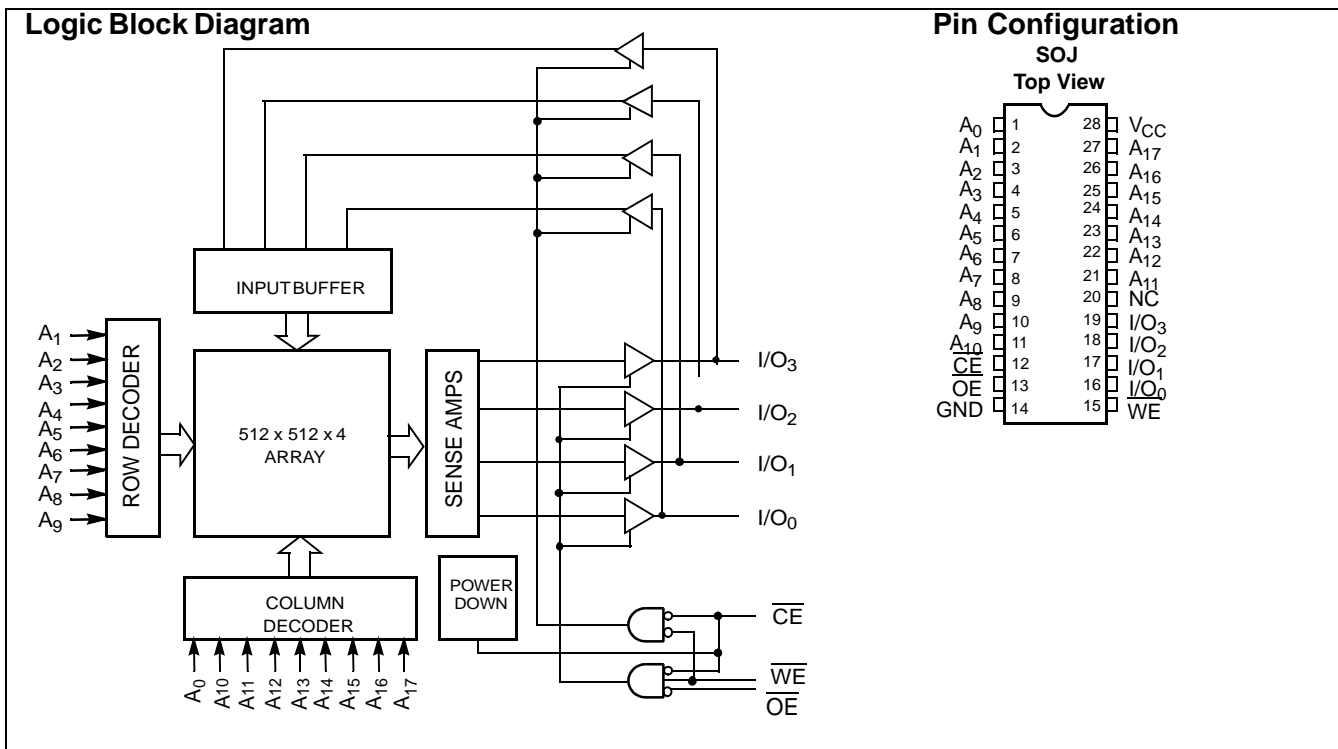

The CY7C106BN and CY7C1006BN are high-performance CMOS static RAMs organized as 262,144 words by 4 bits. Easy memory expansion is provided by an active **LOW** Chip Enable (\overline{CE}), an active **LOW** Output Enable (\overline{OE}), and three-state drivers. These devices have an automatic power-down feature that reduces power consumption by more than 65% when the devices are deselected.

Writing to the devices is accomplished by taking Chip Enable (\overline{CE}) and Write Enable (\overline{WE}) inputs **LOW**. Data on the four I/O pins (I/O_0 through I/O_3) is then written into the location specified on the address pins (A_0 through A_{17}).

Reading from the devices is accomplished by taking Chip Enable (\overline{CE}) and Output Enable (\overline{OE}) **LOW** while forcing Write Enable (\overline{WE}) **HIGH**. Under these conditions, the contents of the memory location specified by the address pins will appear on the four I/O pins.

The four input/output pins (I/O_0 through I/O_3) are placed in a high-impedance state when the devices are deselected (\overline{CE} **HIGH**), the outputs are disabled (\overline{OE} **HIGH**), or during a write operation (\overline{CE} and \overline{WE} **LOW**).

The CY7C106BN is available in a standard 400-mil-wide SOJ; the CY7C1006BN is available in a standard 300-mil-wide SOJ.

Notes:

- Test conditions assume signal transition time of 3 ns or less, timing reference levels of 1.5V, input pulse levels of 0 to 3.0V, and output loading of the specified I_{OL}/I_{OH} and 30-pF load capacitance.
- t_{HZOE}, t_{HZCE}, and t_{HZWE} are specified with a load capacitance of 5 pF as in part (b) of AC Test Loads. Transition is measured ±500 mV from steady-state voltage.
- At any given temperature and voltage condition, t_{HZCE} is less than t_{LZCE}, t_{HZOE} is less than t_{LZOE}, and t_{HZWE} is less than t_{LZWE} for any given device.
- The internal write time of the memory is defined by the overlap of \overline{CE} and \overline{WE} LOW. \overline{CE} and \overline{WE} must be LOW to initiate a write, and the transition of either of these signals can terminate the write. The input data set-up and hold timing should be referenced to the leading edge of the signal that terminates the write.
- The minimum write cycle time for Write Cycle No. 3 (\overline{WE} controlled, \overline{OE} LOW) is the sum of t_{HZWE} and t_{SD}.
