EL2210C/11C, EL2310C/11C, EL2410C/11C Low Cost, Dual, Triple and Quad Video Op Amps

## Features

- Stable at gain of 2 and 100 MHz gain_bandwidth product (EL2211C, EL2311C, \& EL2411C)
- Stable at gain of 1 and 50 MHz gain_bandwidth product
(EL2210C, EL2310C, \&
EL2410C)
- $130 \mathrm{~V} / \mu \mathrm{s}$ slew rate
- Drives $150 \Omega$ load to video levels
- Inputs and outputs operate at negative supply rail
- $\pm 5 \mathrm{~V}$ or +10 V supplies
- -60 dB isolation at 4.2 MHz

## Applications

- Consumer video amplifiers
- Active filters/integrators
- Cost-sensitive applications
- Single supply amplifiers

## General Description

This family of dual, triple, and quad operational amplifiers built using Elantec's Complementary Bipolar process offers unprecedented high frequency performance at a very low cost. They are suitable for any application such as consumer video, where traditional DC performance specifications are of secondary importance to the high frequency specifications. On $\pm 5 \mathrm{~V}$ supplies at a gain of +1 the EL2210C, EL2310C, and EL2410C will drive a $150 \Omega$ load to +2 V , -1 V with a bandwidth of 50 MHz and a channel-to-channel isolation of 60 dB or more. At a gain of +2 , the EL2211C, EL2311C, and EL2411C will drive a $150 \Omega$ load to $+2 \mathrm{~V},-1 \mathrm{~V}$ with a bandwidth of 100 MHz with the same channel-to-channel isolation. All four achieve 0.1 dB bandwidth at 5 MHz .
The power supply operating range is fixed at $\pm 5 \mathrm{~V}$ or $+10 / 0 \mathrm{~V}$. In single supply operation the inputs and outputs will operate to ground. Each amplifier draws only 7 mA of supply current.

## Typical Performance Curves

# EL2210C/11C, EL2310C/11C, EL2410C/11C 

 Low Cost, Dual, Triple and Quad Video Op Amps
## Application Information

## Product Description

The EL2210C, EL2310C, and EL2410C are dual, triple, and quad operational amplifiers stable at a gain of 1 . The EL2211C, EL2311C, and EL2411C are dual, triple, and quad operational amplifiers stable at a gain of 2. All six are built on Elantec's proprietary complimentary process and share the same voltage mode feedback topology. This topology allows them to be used in a variety of applications where current mode feedback amplifiers are not appropriate because of restrictions placed on the feedback elements. These products are especially designed for applications where high bandwidth and good video performance characteristics are desired but the higher cost of more flexible and sophisticated products are prohibitive.

## Power Supplies

These amplifiers are designed to work at a supply voltage difference of 10 V to 12 V . These amplifiers will work on any combination of $\pm$ supplies. All electrical characteristics are measured with $\pm 5 \mathrm{~V}$ supplies. Below 9 V total supply voltage the amplifiers' performance will degrade dramatically. The quiescent current is a direct function of total supply voltage. With a total supply voltage of 12 V the quiescent supply current will increase from a typical 6.8 mA per amplifier to 10 mA per amplifier.

## Output Swing vs Load

Please refer to the simplified block diagram. These amplifiers provide an NPN pull-up transistor output and a passive $1250 \Omega$ pull-down resistor to the most negative supply. In an application where the load is connected to $\mathrm{V}_{\mathrm{S}}$ - the output voltage can swing to within 200 mV of $\mathrm{V}_{\mathrm{S}^{-}}$. In split supply applications where the DC load is connected to ground the negative swing is limited by the voltage divider formed by the load, the internal $1250 \Omega$ resistor and any external pull-down resistor. If $R_{L}$ were $150 \Omega$ then it and the $1250 \Omega$ internal resistor limit the maximum negative swing to

$$
\mathrm{V}_{\mathrm{EE}}=\frac{150}{1250+150}
$$

Or -0.53 V

The negative swing can be increased by adding an external resistor of appropriate value from the output to the negative supply. The simplified block diagram shows an $820 \Omega$ external pull-down resistor. This resistor is in parallel with the internal $1250 \Omega$ resistor. This will increase the negative swing to

$$
\mathrm{V}_{\mathrm{EE}}=150 \div \frac{1250 \times 820}{1250+820}+150
$$

Or -1.16 V

## Power Dissipation and Loading

Without any load and a 10 V supply difference the power dissipation is 70 mW per amplifier. At 12 V supply difference this increases to 105 mW per amplifier. At 12 V this translates to a junction temperature rise above ambient of $33^{\circ} \mathrm{C}$ for the dual and $40^{\circ} \mathrm{C}$ for the quad amplifier. When the amplifiers provide load current the power dissipation can rapidly rise.
In $\pm 5 \mathrm{~V}$ operation each output can drive a grounded $150 \Omega$ load to more than 2 V . This operating condition will not exceed the maximum junction temperature limit as long as the ambient temperature is below $85^{\circ} \mathrm{C}$, the device is soldered in place, and the extra pull-down resistor is $820 \Omega$ or more.
If the load is connected to the most negative voltage (ground in single supply operation) you can easily exceed the absolute maximum die temperature. For example the maximum die temperature should be $150^{\circ} \mathrm{C}$. At a maximum expected ambient temperature of $85^{\circ} \mathrm{C}$, the total allowable power dissipation for the SO8 package would be:

$$
\mathrm{P}_{\mathrm{D}}=\frac{150-85}{160^{\circ} \mathrm{C} / \mathrm{W}}=361 \mathrm{~mW}
$$

At 12 V total supply voltage each amplifier draws a maximum of 10 mA and dissipates $12 \mathrm{~V} * 10 \mathrm{~mA}=120 \mathrm{~mW}$ or 240 mW for the dual amplifier. Which leaves 121 mW of increased power due to the load. If the load were $150 \Omega$ connected to the most negative voltage and the maximum voltage out were $\mathrm{V}_{\mathrm{S}^{-}}+1 \mathrm{~V}$ the load current would be 6.67 mA . Then an extra $146 \mathrm{~mW}((12 \mathrm{~V}-1 \mathrm{~V}) *$ $6.67 \mathrm{~mA} * 2)$ would be dissipated in the EL2210C or

## EL2210C/11C, EL2310C/11C, EL2410C/11C

Low Cost, Dual, Triple and Quad Video Op Amps

EL2211C. The total dual amplifier power dissipation would be $146 \mathrm{~mW}+240 \mathrm{~mW}=386 \mathrm{~mW}$, more than the maximum 361 mW allowed. If the total supply difference were reduced to 10 V , the same calculations would yield 200 mW quiescent power dissipation and 120 mW due to loading. This results in a die temperature of $143^{\circ} \mathrm{C}\left(85^{\circ} \mathrm{C}+58^{\circ} \mathrm{C}\right)$.
In the above example, if the supplies were split $\pm 6 \mathrm{~V}$ and the $150 \Omega$ loads were connected to ground, the load induced power dissipation would drop to 66.7 mW $(6.67 \mathrm{~mA} *(6-1) * 2)$ and the die temperature would be below the rated maximum.

## Video Performance

Following industry standard practices (see EL2044C applications section) these six devices exhibit good differential gain (dG) and good differential phase (dP) with $\pm 5 \mathrm{~V}$ supplies and an external $820 \Omega$ resistor to the negative supply, in a gain of 2 configuration. Driving $75 \Omega$ back terminated cables to standard video levels $(1.428 \mathrm{~V}$ at the amplifier) the EL2210C, EL2310C, and EL2410C have dG of $0.1 \%$ and dP of $0.2^{\circ}$. The EL2211C, EL2311C, and EL2411C have dG of $0.04 \%$ and dP of $0.15^{\circ}$.
Due to the negative swing limitations described above, inverted video at a gain of 2 is just not practical. If swings below ground are required then changing the extra $820 \Omega$ resistor to $500 \Omega$ will allow reasonable dG and dP to approximately -0.75 mV . The EL2211C, EL2311C, and EL2411C will achieve approximately $0.1 \% / 0.4^{\circ}$ between 0 V and -0.75 V . Beyond -0.75 V dG and dP get worse by orders of magnitude.
Differential gain and differential phase are fairly constant for all loads above $150 \Omega$. Differential phase performance will improve by a factor of 3 if the supply voltage is increased to $\pm 6 \mathrm{~V}$.

## Output Drive Capability

None of these devices have short circuit protection. Each output is capable of more than 100 mA into a shorted output. Care must be used in the design to limit the output current with a series resistor.

## Printed-Circuit Layout

The EL2210C/EL2211C/EL2310C/EL2311C/ EL2410C/EL2411C are well behaved, and easy to apply in most applications. However, a few simple techniques will help assure rapid, high quality results. As with any high-frequency device, good PCB layout is necessary for optimum performance. Ground-plane construction is highly recommended, as is good power supply bypassing. A $0.1 \mu \mathrm{~F}$ ceramic capacitor is recommended for bypassing both supplies. Lead lengths should be as short as possible, and bypass capacitors should be as close to the device pins as possible. For good AC performance, parasitic capacitances should be kept to a minimum at both inputs and at the output. Resistor values should be kept under $5 \mathrm{k} \Omega$ because of the RC time constants associated with the parasitic capacitance. Metal-film and carbon resistors are both acceptable, use of wire-wound resistors is not recommended because of their parasitic inductance. Similarly, capacitors should be low-inductance for best performance.
