Description

- The GS809C and 810C are system supervisor circuits designed to monitor V_{CC} in digital systems and provide a reset signal to the host processor when necessary. No external components are required.
- When the processor power supply voltage drops below the reset threshold, the reset output is driven active, in less than 40µs (T_{D1}). Reset is maintained active for a time period (T_{D2}), after the V_{cc} rises above the threshold voltage.
- To prevent jitter, the reset threshold voltage has a built-in hysteresis of 0.4% of V_{TH}.
- The GS809C has an active-low $\overline{reset}$ output, while the GS810C has an active-high reset output. Both devices have push/pull output drives.
- The reset signal is guaranteed valid, down to V_{cc} = 1.0V.
- Low supply current of 3µA makes these devices well suited for battery powered applications. They are designed to reject fast transients from causing false resets.
- Both devices are available in a space-saving SOT-23 package.

Applications

- Computers
- Battery Powered Equipment
- Critical uProcessor and uController power supply monitoring

Features

- Tight reset voltage tolerances ± 1.5%
- 4 reset active timeout period options
- Low quiescent current: < 3µA
- 9 reset threshold options from 2.1V to 4.63V
- $\overline{Reset}$ output guaranteed down to 1.0V
- No external components
- V_{cc} Transient immunity
- Wide temperature range –40°C to +85°C

Supply (V_{CC}) Transients

These devices have a certain immunity to fast negative going transients. The graph titled “Transient Rejection” shows the maximum allowable transient amplitude and duration to avoid triggering an unintended reset. As shown in the graph shorter transients can have larger amplitudes without triggering resets.
