HMS87C1304A / HMS87C1302A

CMOS SINGLE-CHIP 8-BIT MICROCONTROLLER

1. OVERVIEW

1.1 Description

The HMS87C1304A and HMS87C1302A are an advanced CMOS 8-bit microcontroller with 4K/2K bytes of EPROM. The HYUNDAI MicroElectronics HMS87C1304A and HMS87C1302A are powerful microcontroller which provides a highly flexible and cost effective solution to many small applications such as controller for battery charger. The HMS87C1304A and HMS87C1302A provide the following standard features: 4K/2K bytes of EPROM, 128bytes of RAM, 8-bit timer/counter, 8-bit A/D converter, 10-bit high speed PWM output, programmable buzzer driving port, power-on reset circuit, on-chip oscillator and clock circuitry. In addition, the HMS87C1304A and HMS87C1302A supports power saving modes to reduce power consumption.

Device name	EPROM Size	RAM Size	Operatind Voltage	Package
HMS87C1304A	4K bytes	128bytes	2.0 ~ 5.5V	24 PDIP or SOP
HMS87C1302A	2K bytes	128bytes	2.0 ~ 5.5V	24 PDIP or SOP

1.2 Features

- **4K/2K Bytes On-chip Program Memory**

- **128 Bytes of On-chip Data RAM**
  (Included stack memory)

- **Instruction Cycle Time:**
  - 250nS at 8MHz

- **19 Programmable I/O pins**
  (LED direct driving can be source and sink)

- **2.0V to 5.5V Wide Operating Range**

- **One 8-bit A/D Converter**
  - 8 channels

- **One 8-bit Basic Interval Timer**

- **Two 8-bit Timer / Counters**

- **One 10-bit High Speed PWM Outputs**

- **Watchdog timer**

- **Seven Interrupt sources**
  - External input: 2
  - A/D Conversion: 1
  - Timer: 4

- **One Programmable Buzzer Driving port**
  - 500Hz ~ 130kHz

- **Oscillator Type**
  - Crystal
  - Ceramic Resonator
  - RC-oscillation (C can be omit)

- **Power-On Reset**

- **Noise Immunity Circuit**
  - Power Fail Processor

- **Power Down Mode**
  - STOP mode
  - Wake-up Timer mode

1.3 Development Tools

The HMS87C1304A and HMS87C1302A are supported by a full-featured macro assembler, an in-circuit emulator CHOICE-Dr^{TM}.

In Circuit Emulators	CHOICE-Dr.
Assembler	HME Macro Assembler
OTP Writer	Single Writer : Dr. Writer
	4-Gang Writer : Dr.Gang

1.4 Ordering Information

ROM Size	Package Type	Ordering Device Code	Operating Temperature
4K bytes (OTP)	24 PDIP	HMS87C1304A	-20 ~ +85°C
	24 SOP	HMS87C1304A D	
2K bytes (OTP)	24 PDIP	HMS87C1302A	
	24 SOP	HMS87C1302A D

5. PIN FUNCTION

V_{DD}: Supply voltage.

V_{SS}: Circuit ground.

$\overline{RESET}$: Reset the MCU.

X_{IN}: Input to the inverting oscillator amplifier and input to the internal main clock operating circuit.

X_{OUT}: Output from the inverting oscillator amplifier.

RA0~RA7: RA is an 8-bit, CMOS, bidirectional I/O port. RA pins can be used as outputs or inputs according to "1" or "0" written the their Port Direction Register(RAIO).

Port pin	Alternate function
RA0	EC0 (Event Counter Input Source)
RA1	AN1 (Analog Input Port 1)
RA2	AN2 (Analog Input Port 2)
RA3	AN3 (Analog Input Port 3)
RA4	AN4 (Analog Input Port 4)
RA5	AN5 (Analog Input Port 5)
RA6	AN6 (Analog Input Port 6)
RA7	AN7 (Analog Input Port 7)

Table 5-1 RA Port

In addition, RA serves the functions of the various special features in Table 5-1 .

RB0~RB7: RB is a 8-bit, CMOS, bidirectional I/O port. RB pins can be used as outputs or inputs according to "1" or "0" written the their Port Direction Register(RBIO).

RB serves the functions of the various following special features in Table 5-2

Port pin	Alternate function
RB0	AN0 (Analog Input Port 0)
	AVref (External Analog Reference Pin)
RB1	BUZ (Buzzer Driving Output Port)
RB2	INT0 (External Interrupt Input Port 0)
RB3	INT1 (External Interrupt Input Port 1)
RB4	PWM0 (PWM0 Output)
	COMP0 (Timer1 Compare Output)

Table 5-2 RB Port

RC0, RC1: RC is a 2-bit, CMOS, bidirectional I/O port. RC pins can be used as outputs or inputs according to "1" or "0" written the their Port Direction Register(RCIO).

RD0~RD3: RD is a 4-bit, CMOS, bidirectional I/O port. RC pins can be used as outputs or inputs according to "1" or "0" written the their Port Direction Register(RDIO).

PIN NAME	Pin No.	In/Out	Function	
V_{DD}	5	-	Supply voltage	
V_{SS}	18	-	Circuit ground	
$\overline{\text{RESET}}$	17	I	Reset signal input	
X_{IN}	15	I		
X_{OUT}	16	O		
RA0 (EC0)	21	I/O (Input)	8-bit general I/O ports	External Event Counter input 0
RA1 (AN1)	22	I/O (Input)		Analog Input Port 1
RA2 (AN2)	23	I/O (Input)		Analog Input Port 2
RA3 (AN3)	24	I/O (Input)		Analog Input Port 3
RA4 (AN4)	1	I/O (Input)		Analog Input Port 4
RA5 (AN5)	2	I/O (Input)		Analog Input Port 5
RA6 (AN6)	3	I/O (Input)		Analog Input Port 6
RA7 (AN7)	4	I/O (Input)		Analog Input Port 7
RB0 (AVref/AN0)	8	I/O (Input)	5-bit general I/O ports	Analog Input Port 0 / Analog Reference
RB1 (BUZ)	9	I/O (Input)		Buzzer Driving Output
RB2 (INT0)	10	I/O (Input)		External Interrupt Input 0
RB3 (INT1)	11	I/O (Output)		External Interrupt Input 1
RB4 (PWM0/COMP0)	12	I/O (Output/Output)		PWM0 Output or Timer1 Compare Output
RC0	19	I/O	2-bit general I/O ports	
RC1	20	I/O		
RD0	6	I/O	4-bit general I/O ports	
RD1	7	I/O		
RD2	13	I/O		
RD3	14	I/O

7. ELECTRICAL CHARACTERISTICS

7.1 Absolute Maximum Ratings

Supply voltage .... -0.3 to +6.0 V

Storage Temperature ....-40 to +125 °C

Voltage on any pin with respect to Ground (V_{SS})
.... -0.3 to V_{DD}+0.3

Maximum current out of V_{SS} pin ....200 mA

Maximum current into V_{DD} pin ....150 mA

Maximum current sunk by (I_{OL} per I/O Pin) ....25 mA

Maximum output current sourced by (I_{OH} per I/O Pin)
....15 mA

Maximum current (ΣI_{OL}) ....150 mA

Maximum current (ΣI_{OH})..................................... 100 mA

Note: *Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.*

7.2 Recommended Operating Conditions

Parameter	Symbol	Condition	Specifications		Unit
			Min.	Max.	
Supply Voltage	V_{DD}	f_{XIN}=8MHz	4.5	5.5	V
		f_{XIN}=4.2MHz	2.0	5.5	V
Operating Frequency	f_{XIN}	V_{DD}=4.5~5.5V	1	8	MHz
		V_{DD}=2.0~5.5V	1	4.2	MHz
Operating Temperature	T_{OPR}		-20	85	°C

7.3 A/D Converter Characteristics

(T_A=25°C, V_{SS}=0V, V_{DD}=5.12V @f_{XIN}=8MHz, V_{DD}=3.072V @f_{XIN}=4MHz)

Parameter	Symbol	Condition	Specifications			Unit
			Min.	Typ.	Max.	
Analog Input Voltage Range	V_{AIN}	AVREFS=0	V_{SS}	-	V_{DD}	V
		AVREFS=1	V_{SS}	-	V_{REF}	
Analog Power Supply Input Voltage Range	V_{REF}	V_{DD}=5V	3	-	V_{DD}	V

7.6 Typical Characteristics

This graphs and tables provided in this section are for design guidance only and are not tested or guaranteed.

In some graphs or tables the data presented are outside specified operating range (e.g. outside specified V_{DD} range). This is for information only and devices are guaranteed to operate properly only within the specified range.

The data presented in this section is a statistical summary of data collected on units from different lots over a period of time. "Typical" represents the mean of the distribution while "max" or "min" represents (mean + 3σ) and (mean − 3σ) respectively where σ is standard deviation

Preliminary   Jan. 2001
8. MEMORY ORGANIZATION

The HMS87C1304A and HMS87C1302A have separate address spaces for Program memory and Data Memory. Program memory can only be read, not written to. It can be

8.1 Registers

This device has six registers that are the Program Counter (PC), a Accumulator (A), two index registers (X, Y), the Stack Pointer (SP), and the Program Status Word (PSW). The Program Counter consists of 16-bit register.

Figure 8-1 Configuration of Registers

Accumulator: The Accumulator is the 8-bit general purpose register, used for data operation such as transfer, temporary saving, and conditional judgement, etc.

The Accumulator can be used as a 16-bit register with Y Register as shown below.

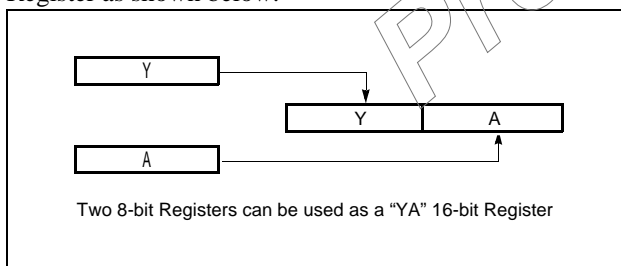

Two 8-bit Registers can be used as a "YA" 16-bit Register

Figure 8-2 Configuration of YA 16-bit Register

X, Y Registers: In the addressing mode which uses these index registers, the register contents are added to the specified address, which becomes the actual address. These modes are extremely effective for referencing subroutine tables and memory tables. The index registers also have increment, decrement, comparison and data transfer functions, and they can be used as simple accumulators.

Stack Pointer: The Stack Pointer is an 8-bit register used for occurrence interrupts and calling out subroutines. Stack Pointer identifies the location in the stack to be accessed (save or restore).

up to 4K /8K bytes of Program memory. Data memory can be read and written to up to 192 bytes including the stack area.

Generally, SP is automatically updated when a subroutine call is executed or an interrupt is accepted. However, if it is used in excess of the stack area permitted by the data memory allocating configuration, the user-processed data may be lost.

The stack can be located at any position within 00_H to $7F_H$ of the internal data memory. The SP is not initialized by hardware, requiring to write the initial value (the location with which the use of the stack starts) by using the initialization routine. Normally, the initial value of "$7F_H$" is used.

Hardware fixed
Note: *The Stack Pointer must be initialized by software because its value is undefined after RESET.*
Example: To initialize the SP
LDX   #07FH
TXSP   ; SP ← $7F_H$

Program Counter: The Program Counter is a 16-bit wide which consists of two 8-bit registers, PCH and PCL. This counter indicates the address of the next instruction to be executed. In reset state, the program counter has reset routine address (PC_H:$0FF_H$, PC_L:$0FE_H$).
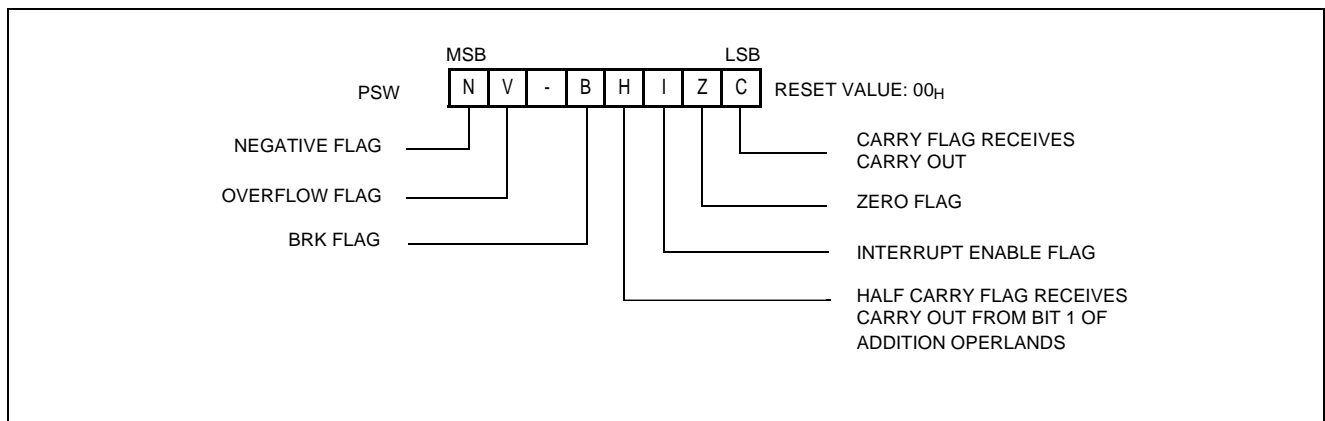

Program Status Word: The Program Status Word (PSW) contains several bits that reflect the current state of the CPU. The PSW is described in Figure 8-3 . It contains the Negative flag, the Overflow flag, the Break flag the Half Carry (for BCD operation), the Interrupt enable flag, the Zero flag, and the Carry flag.

[Carry flag C]

This flag stores any carry or borrow from the ALU of CPU after an arithmetic operation and is also changed by the Shift Instruction or Rotate Instruction.

[Zero flag Z]

This flag is set when the result of an arithmetic operation or data transfer is "0" and is cleared by any other result.

```
                    MSB                    LSB
         PSW        N  V  -  B  H  I  Z  C     RESET VALUE: 00H

NEGATIVE FLAG                                  CARRY FLAG RECEIVES
                                               CARRY OUT

OVERFLOW FLAG                                  ZERO FLAG

BRK FLAG                                       INTERRUPT ENABLE FLAG

                                               HALF CARRY FLAG RECEIVES
                                               CARRY OUT FROM BIT 1 OF
                                               ADDITION OPERLANDS
```

Figure 8-3 PSW (Program Status Word) Register

[Interrupt disable flag I]

This flag enables/disables all interrupts except interrupt caused by Reset or software BRK instruction. All interrupts are disabled when cleared to "0". This flag immediately becomes "0" when an interrupt is served. It is set by the EI instruction and cleared by the DI instruction.

[Half carry flag H]

After operation, this is set when there is a carry from bit 3 of ALU or there is no borrow from bit 4 of ALU. This bit can not be set or cleared except CLRV instruction with Overflow flag (V).

[Break flag B]

This flag is set by software BRK instruction to distinguish BRK from TCALL instruction with the same vector address.

[Overflow flag V]

This flag is set to "1" when an overflow occurs as the result of an arithmetic operation involving signs. An overflow occurs when the result of an addition or subtraction exceeds +127($7F_H$) or -128(80_H). The CLRV instruction clears the overflow flag. There is no set instruction. When the BIT instruction is executed, bit 6 of memory is copied to this flag.

[Negative flag N]

This flag is set to match the sign bit (bit 7) status of the result of a data or arithmetic operation. When the BIT instruction is executed, bit 7 of memory is copied to this flag.

8.2 Program Memory

A 16-bit program counter is capable of addressing up to 64K bytes, but these devices have 4K/2K bytes program memory space only physically implemented. Accessing a location above $FFFF_H$ will cause a wrap-around to 0000_H.

Figure 8-4 , shows a map of Program Memory. After reset, the CPU begins execution from reset vector which is stored in address $FFFE_H$ and $FFFF_H$ as shown in Figure 8-5 .

As shown in Figure 8-4 , each area is assigned a fixed location in Program Memory. Program Memory area contains the user program.

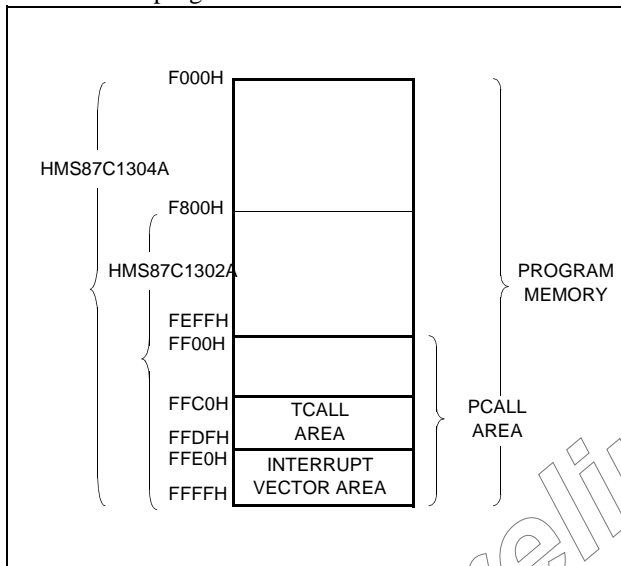

Figure 8-4 Program Memory Map

Page Call (PCALL) area contains subroutine program to reduce program byte length by using 2 bytes PCALL instead of 3 bytes CALL instruction. If it is frequently called, it is more useful to save program byte length.

Table Call (TCALL) causes the CPU to jump to each TCALL address, where it commences the execution of the service routine. The Table Call service area spaces 2-byte for every TCALL: $0FFC0_H$ for TCALL15, $0FFC2_H$ for TCALL14, etc., as shown in Figure 8-6 .

Example: Usage of TCALL

```
LDA      #5
         TCALL  0FH         ;1BYTE INSTRUCTION
         :                  ;INSTEAD OF 3 BYTES
         :                  ;NORMAL CALL
;
;TABLE CALL ROUTINE
;
FUNC_A:  LDA    LRG0
         RET
;
FUNC_B:  LDA    LRG1    ②  ①
         RET
;
;TABLE CALL ADD. AREA
;
         ORG    0FFC0H            ;TCALL ADDRESS AREA
         DW     FUNC_A
         DW     FUNC_B
```

The interrupt causes the CPU to jump to specific location, where it commences the execution of the service routine. The External interrupt 0, for example, is assigned to location $0FFFA_H$. The interrupt service locations spaces 2-byte interval: $0FFF8_H$ and $0FFF9_H$ for External Interrupt 1, $0FFFA_H$ and $0FFFB_H$ for External Interrupt 0, etc.

As for the area from $0FF00_H$ to $0FFFF_H$, if any area of them is not going to be used, its service location is available as general purpose Program Memory.

NOTE:
"-" means reserved area.

```

Figure 8-7 Data Memory Map

User Memory

The HMS87C1304A and HMS87C1302A has 128×8 bits for the user memory (RAM).

Control Registers

The control registers are used by the CPU and Peripheral function blocks for controlling the desired operation of the device. Therefore these registers contain control and status bits for the interrupt system, the timer/ counters, analog to digital converters and I/O ports. The control registers are in address range of $0C0_H$ to $0FF_H$.

Note that unoccupied addresses may not be implemented on the chip. Read accesses to these addresses will in general return random data, and write accesses will have an indeterminate effect.

More detailed informations of each register are explained in each peripheral section.

Note: *Write only registers can not be accessed by bit manipulation instruction. Do not use read-modify-write instruction. Use byte manipulation instruction.*

Example; To write at CKCTLR

```
LDM    CKCTLR,#09H ;Divide ratio ÷16
```

Address	Symbol	R/W	RESET Value	Addressing mode

Table 8-1 Control Registers

1. "byte, bit" means that register can be addressed by not only bit but byte manipulation instruction.
2. "byte" means that register can be addressed by only byte manipulation instruction. On the other hand, do not use any read-modify-write instruction such as bit manipulation for clearing bit.

Note: *Several names are given at same address. Refer to below table.*

Addr.	When read			When write	
	Timer Mode	Capture Mode	PWM Mode	Timer Mode	PWM Mode
D1H	T0	CDR0	-	TDR0	-
D3H	-			TDR1	T1PPR
D4H	T1	CDR1	T1PDR	-	T1PDR
ECH	BITR			CKCTLR	

Table 8-2 Various Register Name in Same Address

Stack Area

The stack provides the area where the return address is saved before a jump is performed during the processing routine at the execution of a subroutine call instruction or the acceptance of an interrupt.

When returning from the processing routine, executing the subroutine return instruction [RET] restores the contents of the program counter from the stack; executing the interrupt return instruction [RETI] restores the contents of the program counter and flags.

The save/restore locations in the stack are determined by the stack pointed (SP). The SP is automatically decreased after the saving, and increased before the restoring. This means the value of the SP indicates the stack location number for the next save.

Table 8-3 Control Registers of HMS87C1304A and HMS87C1302A

These registers of shaded area can not be accessed by bit manipulation instruction as "SET1, CLR1", but should be accessed by register operation instruction as "LDM dp,#imm".

1. The register BITR and CKCTLR are located at same address. Address ECH is read as BITR, written to CKCTLR.
2. The register PFDR only be implemented on devices, not on In-circuit Emulator.

8.4 Addressing Mode

The HMS87C1304A and HMS87C1302A uses six addressing modes;

- **Register addressing**

- **Immediate addressing**

- **Direct page addressing**

- **Absolute addressing**

- **Indexed addressing**

- **Register-indirect addressing**

(1) Register Addressing

Register addressing accesses the A, X, Y, C and PSW.
(2) Immediate Addressing → #imm

In this mode, second byte (operand) is accessed as a data immediately.

Example:

```
0435     ADC     #35H
```

```
E45535   LDM     35H,#55H
```

(3) Direct Page Addressing → dp

In this mode, a address is specified within direct page.

Example;

```
C535     LDA     35H          ;A ←RAM[35H]
```

(4) Absolute Addressing → !abs

Absolute addressing sets corresponding memory data to Data, i.e. second byte(Operand I) of command becomes lower level address and third byte (Operand II) becomes upper level address.
With 3 bytes command, it is possible to access to whole memory area.

ADC, AND, CMP, CMPX, CMPY, EOR, LDA, LDX, LDY, OR, SBC, STA, STX, STY
Example;

```
0735F0   ADC     !0F035H      ;A ←ROM[0F035H]
```
The operation within data memory (RAM)
ASL, BIT, DEC, INC, LSR, ROL, ROR

Example; Addressing accesses the address 0135$_H$.
```
983500    INC    !0035H      ;A ←RAM[035H]
```

X indexed direct page, auto increment→ {X}+

In this mode, a address is specified within direct page by
the X register and the content of X is increased by 1.

LDA, STA

Example; X=35$_H$
```
DB      LDA    {X}+
```

(5) Indexed Addressing

X indexed direct page (no offset) → {X}

In this mode, a address is specified by the X register.

ADC, AND, CMP, EOR, LDA, OR, SBC, STA, XMA

Example; X=15$_H$
```
D4      LDA    {X}         ;ACC←RAM[X].
```

X indexed direct page (8 bit offset) → dp+X

This address value is the second byte (Operand) of com-
mand plus the data of X-register. And it assigns the mem-
ory in Direct page.

ADC, AND, CMP, EOR, LDA, LDY, OR, SBC, STA
STY, XMA, ASL, DEC, INC, LSR, ROL, ROR

Example; X=015$_H$

```
C645    LDA    45H+X
```

Y indexed direct page (8 bit offset) → dp+Y

This address value is the second byte (Operand) of command plus the data of Y-register, which assigns Memory in Direct page.
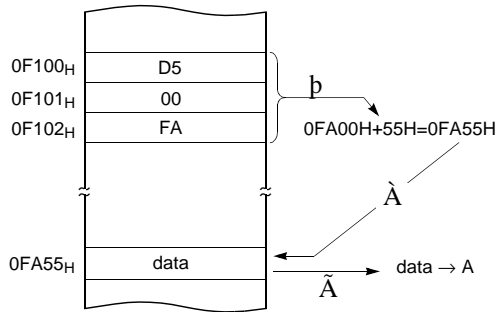

This is same with above (2). Use Y register instead of X.
Y indexed absolute →!abs+Y

Sets the value of 16-bit absolute address plus Y-register data as Memory. This addressing mode can specify memory in whole area.

Example; $Y=55_H$

```
D500FA   LDA   !0FA00H+Y
```

(6) Indirect Addressing

Direct page indirect → [dp]

Assigns data address to use for accomplishing command which sets memory data(or pair memory) by Operand. Also index can be used with Index register X,Y.
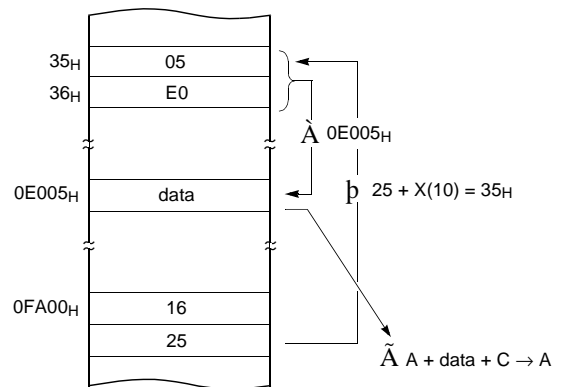

JMP, CALL

Example;

```
3F35    JMP   [35H]
```

X indexed indirect → [dp+X]

Processes memory data as Data, assigned by 16-bit pair memory which is determined by pair data [dp+X+1][dp+X] Operand plus X-register data in Direct page.

ADC, AND, CMP, EOR, LDA, OR, SBC, STA

Example; $X=10_H$
```
1625    ADC   [25H+X]
```

Y indexed indirect → [dp]+Y

Processes memory data as Data, assigned by the data
[dp+1][dp] of 16-bit pair memory paired by Operand in Direct page plus Y-register data.

ADC, AND, CMP, EOR, LDA, OR, SBC, STA

Example; Y=10$_H$
```
1725    ADC   [25H]+Y
```

Absolute indirect → [!abs]

The program jumps to address specified by 16-bit absolute
address.

JMP

Example;

```
1F25E0  JMP   [!0C025H]
```

9. I/O PORTS

The HMS87C1304A and HMS87C1302A has four ports, RA, RB, RC and RD. These ports pins may be multiplexed with an alternate function for the peripheral features on the device. In general, when a initial reset state, all ports are used as a general purpose input port.

All pins have data direction registers which can set these ports as output or input. A "1" in the port direction register defines the corresponding port pin as output. Conversely, write "0" to the corresponding bit to specify as an input pin. For example, to use the even numbered bit of RA as output ports and the odd numbered bits as input ports, write "55_H" to address $C1_H$ (RA direction register) during initial setting as shown in Figure 9-1 .
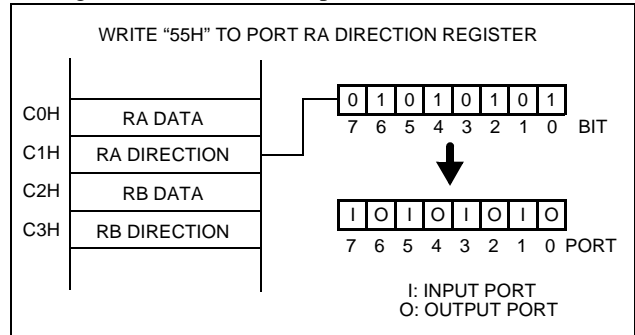

9.1 RA and RAIO registers

 RA is an 8-bit bidirectional I/O port (address $C0_H$). Each port can be set individually as input and output through the RAIO register (address $C1_H$).

RA7~RA1 ports are multiplexed with Analog Input Port (AN7~AN1) and RA0 port is multiplexed with Event Counter Input Port (EC0).

Figure 9-2   Registers of Port RA

The control register RAFUNC (address CA_H) controls to

Reading data register reads the status of the pins whereas writing to it will write to the port latch.

Figure 9-1 Example of port I/O assignment

select alternate function. After reset, this value is "0", port may be used as general I/O ports. To select alternate function such as Analog Input or External Event Counter Input, write "1" to the corresponding bit of RAFUNC.Regardless of the direction register RAIO, RAFUNC is selected to use as alternate functions, port pin can be used as a corresponding alternate features (RA0/EC0 is controlled by RB-FUNC)
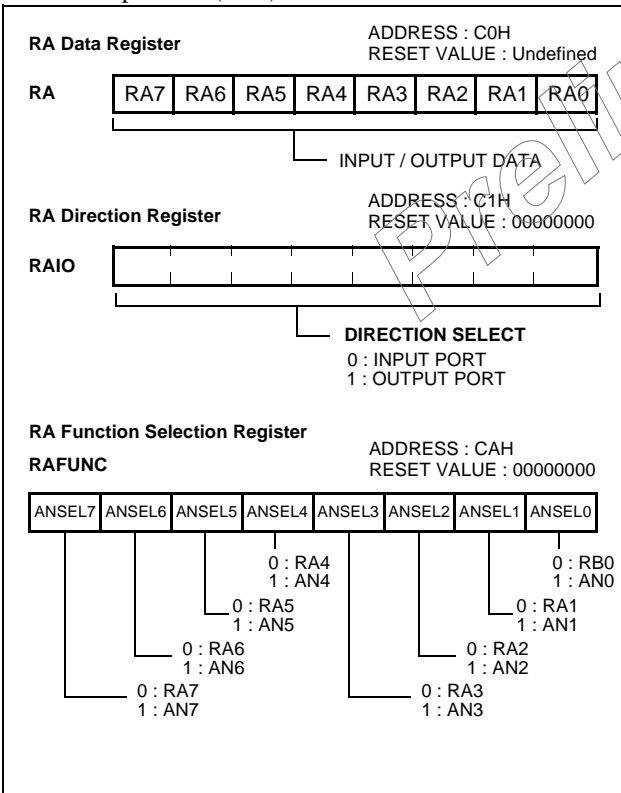

PORT	RAFUNC.7~0	Description
RA7/AN7	0	RA7 (Normal I/O Port)
	1	AN7 (ADS2~0=111)
RA6/AN6	0	RA6 (Normal I/O Port)
	1	AN6 (ADS2~0=110)
RA5/AN5	0	RA5 (Normal I/O Port)
	1	AN5 (ADS2~0=101)
RA4/AN4	0	RA4 (Normal I/O Port)
	1	AN4 (ADS2~0=100)
RA3/AN3	0	RA3 (Normal I/O Port)
	1	AN3 (ADS2~0=011)
RA2/AN2	0	RA2 (Normal I/O Port)
	1	AN2 (ADS2~0=010)
RA1/AN1	0	RA1 (Normal I/O Port)
	1	AN1 (ADS2~0=001)
RA0/EC0[1]		RA0 (Normal I/O Port)
		EC0 (T0CK2~0=111)

1. This port is not an Analog Input port, but Event Counter clock source input port. ECO is controlled by setting TOCK2~0 = 111. The bit RAFUNC.0 (ANSEL0) controls the RB0/AN0/AVref port (Refer to Port RB).

9.2 RB and RBIO registers

RB is a 5-bit bidirectional I/O port (address C2$_H$). Each pin can be set individually as input and output through the RBIO register (address C3$_H$). In addition, Port RB is multiplexed with various special features. The control register RBFUNC (address CB$_H$) controls to select alternate func-

tion. After reset, this value is "0", port may be used as general I/O ports. To select alternate function such as External interrupt or Timer compare output, write "1" to the corresponding bit of RBFUNC.
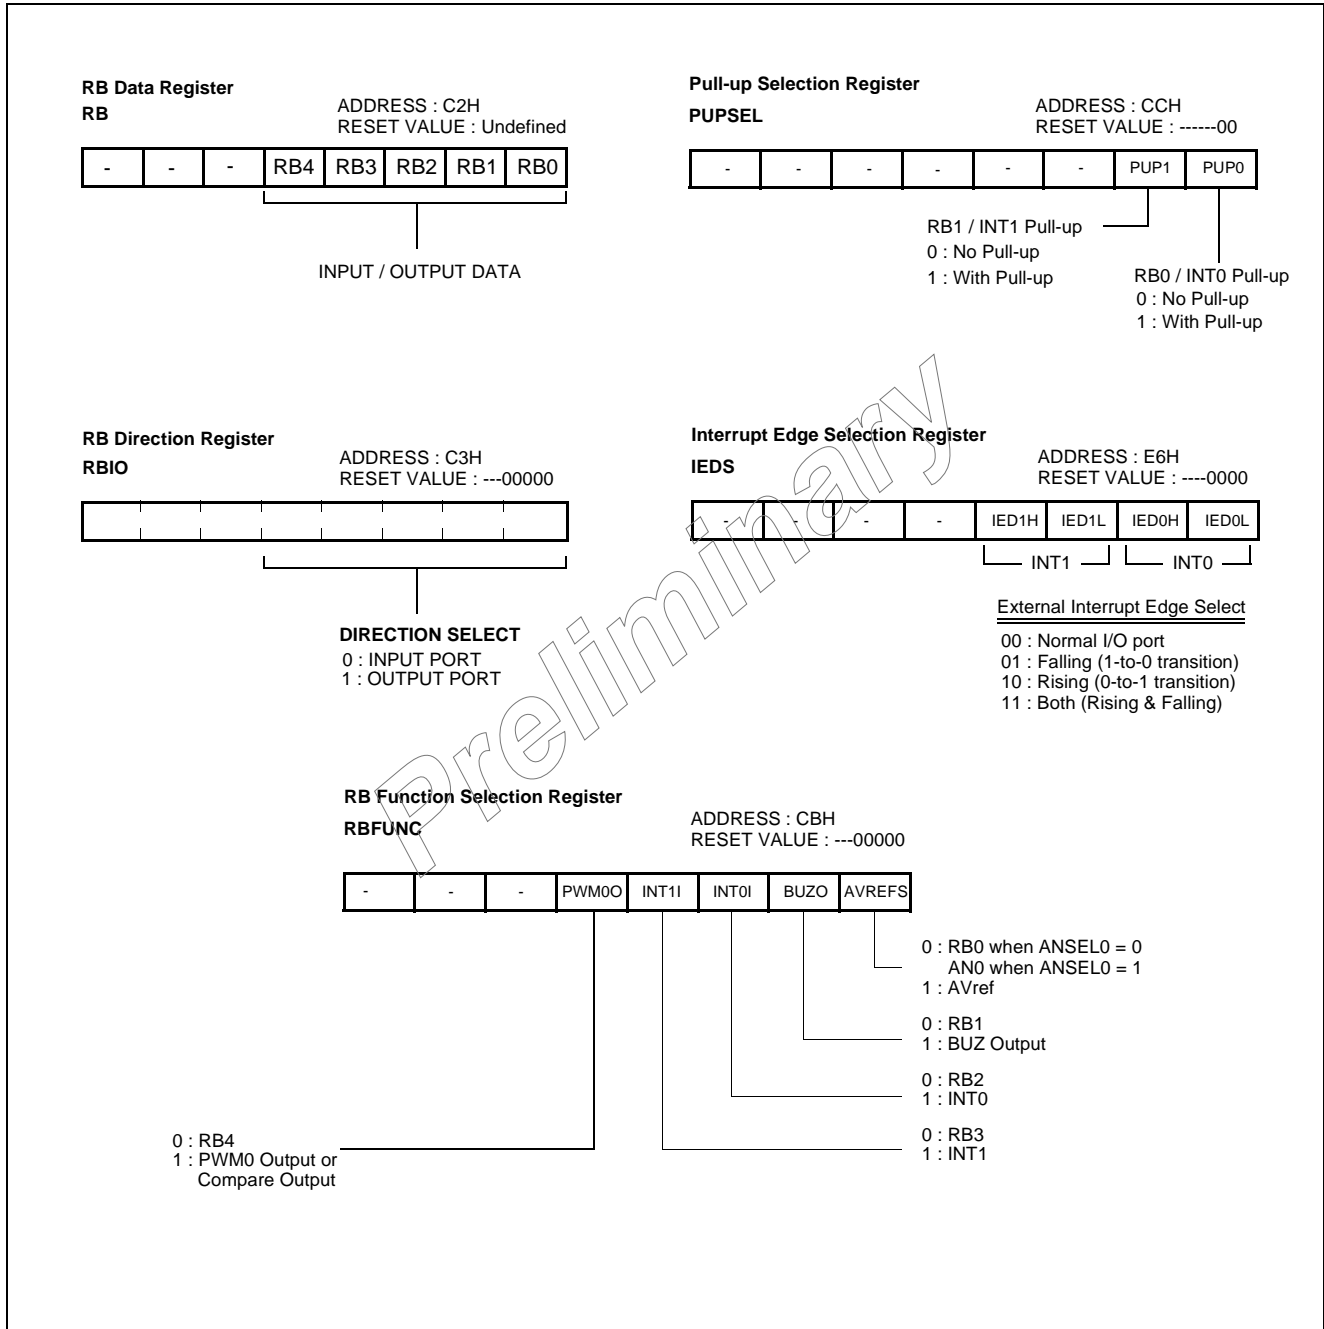

Figure 9-3   Registers of Port RB

Regardless of the direction register RBIO, RBFUNC is selected to use as alternate functions, port pin can be used as

a corresponding alternate features.

PORT	RBFUNC.4~0	Description
RB4/ PWM0/ COMP0	0	RB4 (Normal I/O Port)
	1	PWM0 Output / Timer1 Compare Output
RB3/INT1	0	RB3 (Normal I/O Port)
	1	External Interrupt Input 1
RB2/INT0	0	RB2 (Normal I/O Port)
	1	External Interrupt Input 0
RB1/BUZ	0	RB1 (Normal I/O Port)
	1	Buzzer Output
RB0/AN0/ AVref	0[1]	RB0 (Normal I/O Port)/ AN0 (ANSEL0=1)
	1[2]	External Analog Reference Voltage

1. When ANSEL0 = "0", this port is defined for normal I/O port (RB0).
   When ANSEL0 = "1" and ADS2~0 = "000", this port can be used Analog Input Port (AN0).
2. When this bit set to "1", this port defined for AVref, so it can not be used Analog Input Port AN0 and Normal I/O Port RB0.

9.3 RC and RCIO registers

RC is a 2-bit bidirectional I/O port (address C4$_H$). Each pin can be set individually as input and output through the RCIO register (address C5$_H$).

RC Data Register   ADDRESS : C4H
                          RESET VALUE : Undefined

0 : INPUT PORT
1 : OUTPUT PORT

Figure 9-5 Registers of Port RD

10. CLOCK GENERATOR

The clock generator produces the basic clock pulses which provide the system clock to be supplied to the CPU and peripheral hardware. The main system clock oscillator oscillates with a crystal resonator or a ceramic resonator connected to the

Xin and Xout pins. External clocks can be input to the main system clock oscillator. In this case, input a clock signal to the Xin pin and open the Xout pin.

Figure 10-1   Block Diagram of Clock Pulse Generator

10.1 Oscillation Circuit

X_{IN} and X_{OUT} are the input and output, respectively, a inverting amplifier which can be set for use as an on-chip oscillator, as shown in Figure 10-2 .

Recommended: C1, C2 = 30pF±10pF for Crystals
R1 = 1MΩ

Figure 10-2   Oscillator Connections

To drive the device from an external clock source, Xout should be left unconnected while Xin is driven as shown in Figure 10-3 . There are no requirements on the duty cycle of the external clock signal, since the input to the internal clocking circuitry is through a divide-by-two flip-flop, but minimum and maximum high and low times specified on the data sheet must be observed.
Oscillation circuit is designed to be used either with a ceramic resonator or crystal oscillator. Since each crystal and ceramic resonator have their own characteristics, the user should consult the crystal manufacturer for appropriate

values of external components.

Figure 10-3 External Clock Connections

Note: *When using a system clock oscillator, carry out wiring in the broken line area in Figure 10-2 to prevent any effects from wiring capacities.*
- Minimize the wiring length.
- Do not allow wiring to intersect with other signal conductors.
- Do not allow wiring to come near changing high current.
- Set the potential of the grounding position of the oscillator capacitor to that of Vss. Do not ground to any ground pattern where high current is present.
- Do not fetch signals from the oscillator.

In addition, the HMS87C1304A and HMS87C1302A has an ability for the external RC oscillated operation. It offers additional cost savings for **timing insensitive applica-**

tions. The RC oscillator frequency is a function of the supply voltage, the external resistor (Rext) and capacitor (Cext) values, and the operating temperature.

The user needs to take into account variation due to tolerance of external R and C components used. Figure 10-4 shows how the RC combination is connected to the HMS87C1304A or HMS87C1302A.
Figure 10-4 RC Oscillator Connections

The oscillator frequency, divided by 4, is output from the Xout pin, and can be used for test purpose or to synchroze other logic.

To set the RC oscillation, it should be programmed RCOPT bit to "1" to CONFIG ($0FF0_H$). (Refer to DEVICE CONFIGURATION AREA)

Preliminary

11. Basic Interval Timer

The HMS87C1304A and HMS87C1302A has one 8-bit Basic Interval Timer that is free-run, can not stop. Block diagram is shown in Figure 11-1 .The 8-bit Basic interval timer register (BITR) is increased every internal count pulse which is divided by prescaler. Since prescaler has divided ratio by 8 to 1024, the count rate is 1/8 to 1/1024 of the oscillator frequency. As the count overflows from FF_H to 00_H, this overflow causes to generate the Basic interval timer interrupt. The BITF is interrupt request flag of Basic interval timer.

When write "1" to bit BTCL of CKCTLR, BITR register is cleared to "0" and restart to count-up. The bit BTCL becomes "0" after one machine cycle by hardware.

If the STOP instruction executed after writing "1" to bit WAKEUP of CKCTLR, it goes into the wake-up timer mode. In this mode, all of the block is halted except the oscillator, prescaler (only fxin÷2048) and Timer0.

If the STOP instruction executed after writing "1" to bit RCWDT of CKCTLR, it goes into the internal RC oscillated watchdog timer mode. In this mode, all of the block is halted except the internal RC oscillator, Basic Interval Timer and Watchdog Timer. More detail informations are explained in Power Saving Function. The bit WDTON decides Watchdog Timer or the normal 7-bit timer

Note: *All control bits of Basic interval timer are in CKCTLR register which is located at same address of BITR (address EC_H). Address EC_H is read as BITR, written to CKCTLR. Therefore, the CKCTLR can not be accessed by bit manipulation instruction..*

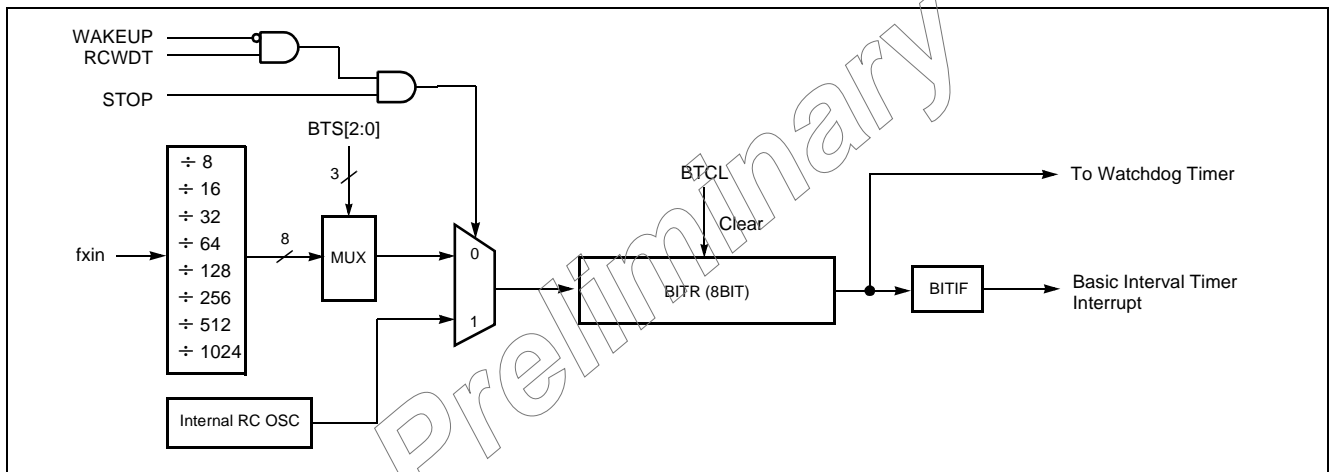

Figure 11-1 Block Diagram of Basic Interval Timer

Figure 11-2 CKCTLR: Clock Control Register

12. TIMER / COUNTER

The HMS87C1304A and HMS87C1302A has two Timer/Counter registers. Each module can generate an interrupt to indicate that an event has occurred (i.e. timer match).

Timer 0 and Timer 1 can be used either the two 8-bit Timer/Counter or one 16-bit Timer/Counter by combining them.

In the "timer" function, the register is increased every internal clock input. Thus, one can think of it as counting internal clock input. Since a least clock consists of 2 and most clock consists of 2048 oscillator periods, the count rate is 1/2 to 1/2048 of the oscillator frequency in Timer0. And Timer1 can use the same clock source too. In addition, Timer1 has more fast clock source (1/1 to 1/8).

In the "counter" function, the register is increased in re-

sponse to a 0-to-1 (rising edge) transition at its corresponding external input pin, EC0(Timer 0).

In addition the "capture" function, the register is increased in response external interrupt same with timer function. When external interrupt edge input, the count register is captured into capture data register CDRx.

Timer1 is shared with "PWM" function and "Compare output" function

It has seven operating modes: "8-bit timer/counter", "16-bit timer/counter", "8-bit capture", "16-bit capture", "8-bit compare output", "16-bit compare output" and "10-bit PWM" which are selected by bit in Timer mode register TMx as shown in Figure 12-1 and Table 12-1 .

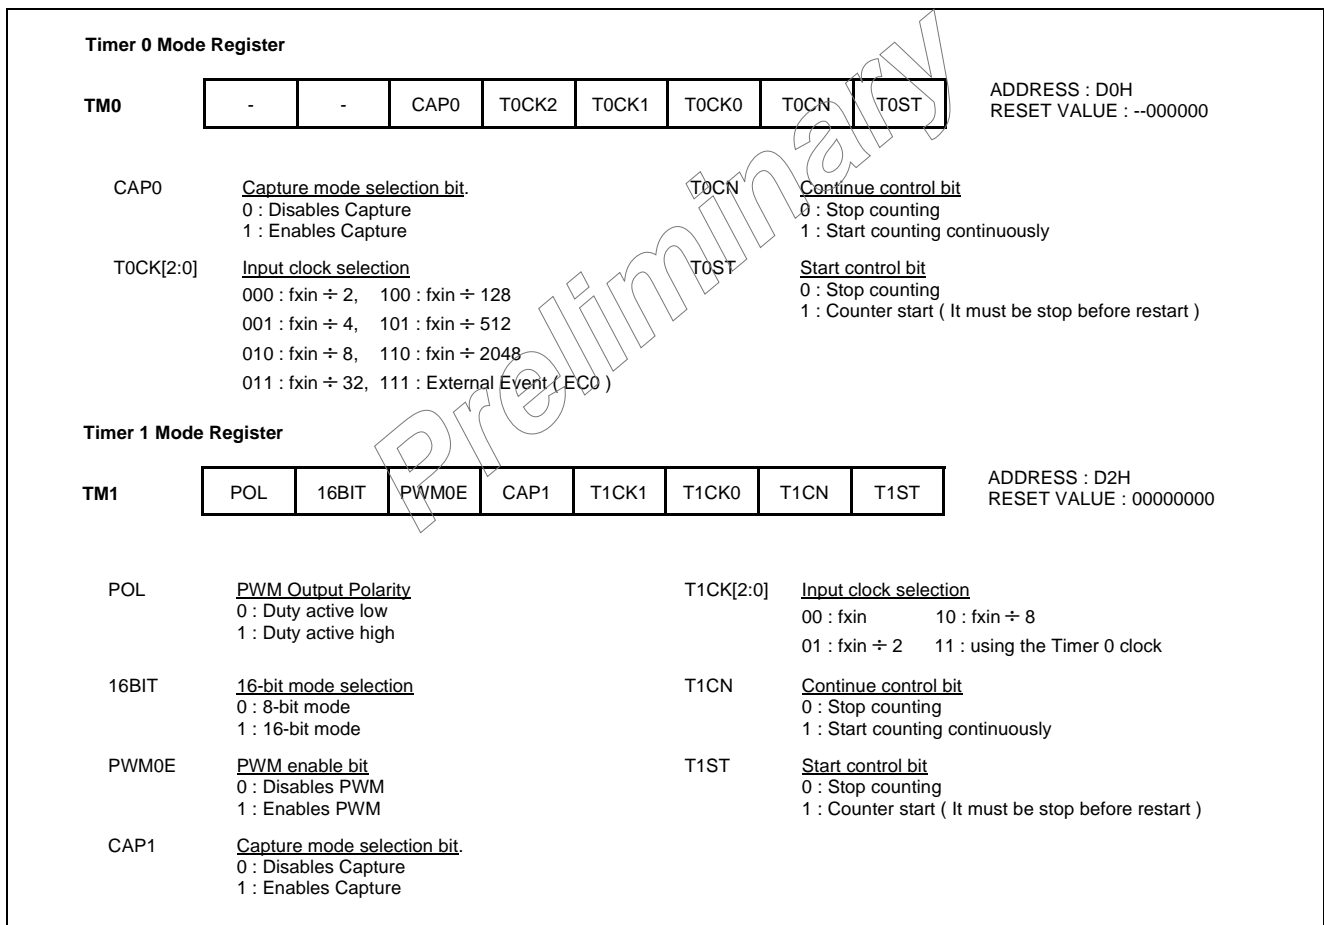

Timer 0 Mode Register

TM0	-	-	CAP0	T0CK2	T0CK1	T0CK0	T0CN	T0ST

ADDRESS : D0H
RESET VALUE : --000000

CAP0 — Capture mode selection bit.
0 : Disables Capture
1 : Enables Capture

T0CK[2:0] — Input clock selection
000 : fxin ÷ 2,   100 : fxin ÷ 128
001 : fxin ÷ 4,   101 : fxin ÷ 512
010 : fxin ÷ 8,   110 : fxin ÷ 2048
011 : fxin ÷ 32,   111 : External Event (EC0)

T0CN — Continue control bit
0 : Stop counting
1 : Start counting continuously

T0ST — Start control bit
0 : Stop counting
1 : Counter start (It must be stop before restart)

Timer 1 Mode Register

Table 12-1 Operating Modes of Timer 0 and Timer 1

1. X: The value "0" or "1" corresponding your operation.

12.1 8-bit Timer/Counter Mode

The HMS87C1304A and HMS87C1302A has four 8-bit Timer/Counters, Timer 0 and Timer 1 as shown in Figure 12-2 .

The "timer" or "counter" function is selected by mode reg-isters TMx as shown in Figure 12-1 and Table 12-1 . To use as an 8-bit timer/counter mode, bit CAP0 of TM0 is cleared to "0" and bits 16BIT of TM1 should be cleared to "0"(Table 12-1).

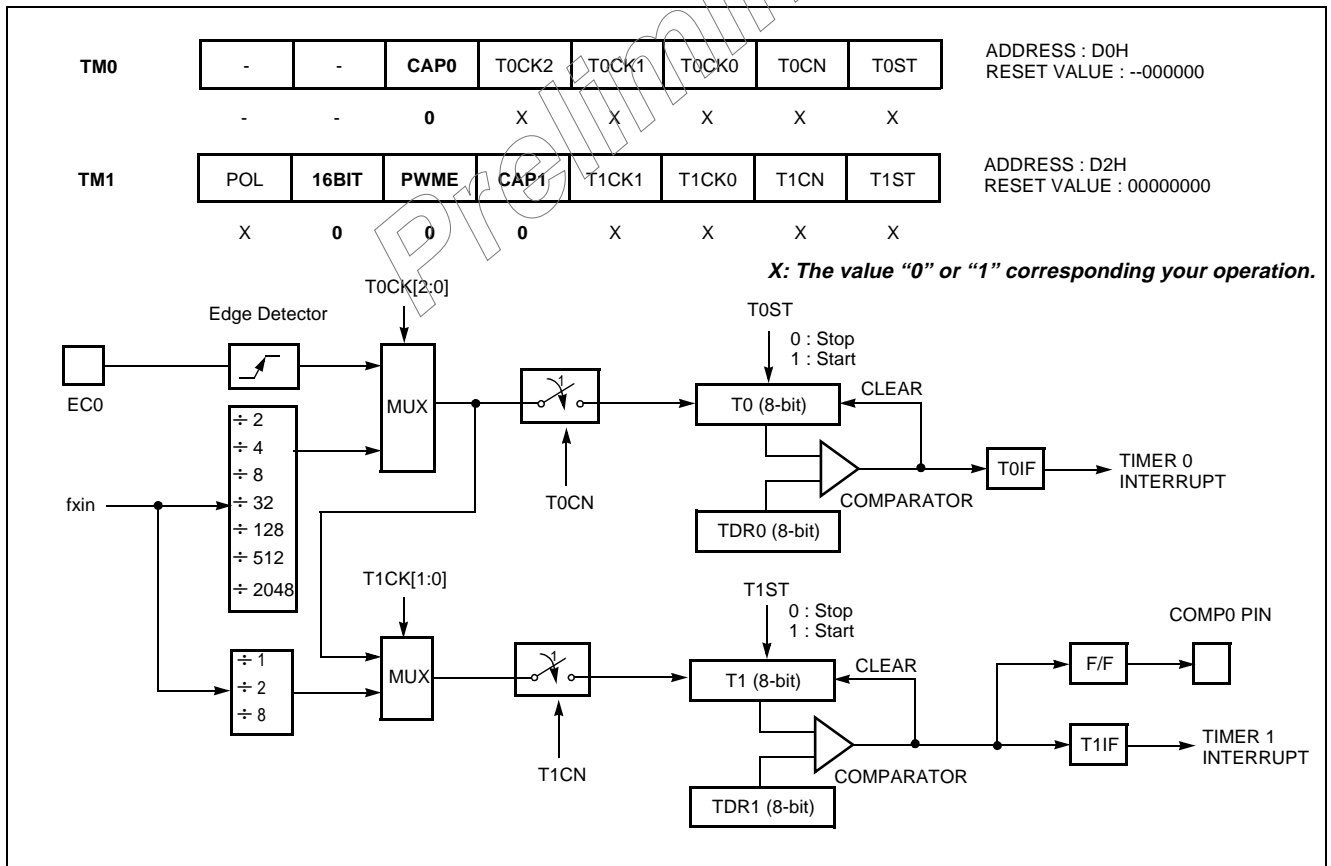

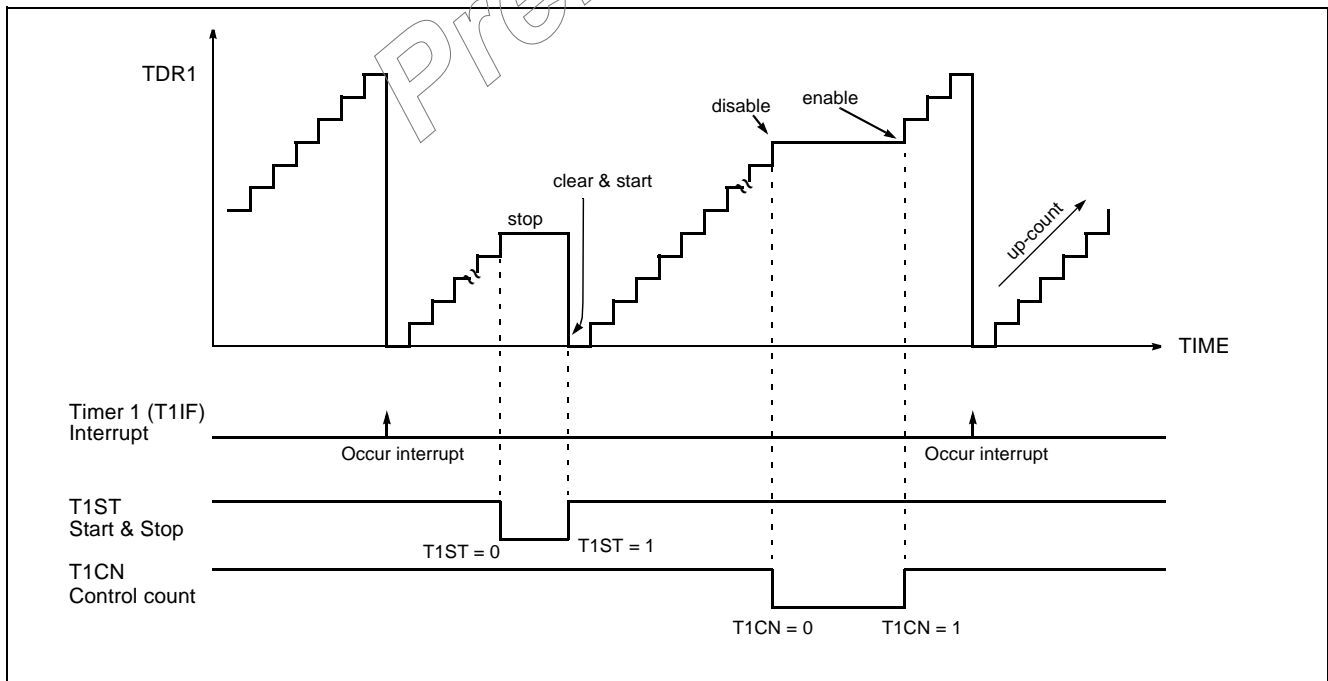

Figure 12-2   8-bit Timer / Counter Mode

These timers have each 8-bit count register and data register. The count register is increased by every internal or external clock input. The internal clock has a prescaler divide ratio option of 2, 4, 8, 32,128, 512, 2048 (selected by control bits T0CK2, T0CK1 and T0CK0 of register TM0) and 1, 2, 8 (selected by control bits T1CK1 and T1CK0 of register TM1). In the Timer 0, timer register T0 increases from 00_H until it matches TDR0 and then reset to 00_H. The match output of Timer 0 generates Timer 0 interrupt

(latched in T0F bit). As TDRx and Tx register are in same address, when reading it as a Tx, written to TDRx.

In counter function, the counter is increased every 0-to 1 (rising edge) transition of EC0 pin. In order to use counter function, the bit RA0 of the RA Direction Register RAIO is set to "0". The Timer 0 can be used as a counter by pin EC0 input, but Timer 1 can not.

Figure 12-3 Counting Example of Timer Data Registers

Figure 12-4 Timer Count Operation

Preliminary

12.2 16-bit Timer/Counter Mode

The Timer register is being run with 16 bits. A 16-bit timer/counter register T0, T1 are increased from 0000$_H$ until it matches TDR0, TDR1 and then resets to 0000$_H$. The match output generates Timer 0 interrupt not Timer 1 interrupt.

The clock source of the Timer 0 is selected either internal or external clock by bit T0CK2, T0CK1 and T0SL0.

In 16-bit mode, the bits T1CK1,T1CK0 and 16BIT of TM1 should be set to "1" respectively.

X: The value "0" or "1" corresponding your operation.

Figure 12-5   16-bit Timer / Counter Mode

12.3 8-bit Compare Output (16-bit)

The HMS87C1304A and HMS87C1302A has a function of Timer Compare Output. To pulse out, the timer match can goes to port pin(COMP0) as shown in Figure 12-2 and Figure 12-5 . Thus, pulse out is generated by the timer match. These operation is implemented to pin, RB4/COMP0/PWM.

This pin output the signal having a 50: 50 duty square

wave, and output frequency is same as below equation.

$$f_{COMP} = \frac{\text{Oscillation Frequency}}{2 \times \text{Prescaler Value} \times (TDR + 1)}$$

In this mode, the bit PWMO of RB function register (RB-FUNC) should be set to "1", and the bit PWME of timer1 mode register (TM1) should be set to "0".

In addition, 16-bit Compare output mode is available, also.

12.4 8-bit Capture Mode

The Timer 0 capture mode is set by bit CAP0 of timer mode register TM0 (bit CAP1 of timer mode register TM1 for Timer 1) as shown in Figure 12-6 .

As mentioned above, not only Timer 0 but Timer 1 can also

be used as a capture mode.

The Timer/Counter register is increased in response internal or external input. This counting function is same with normal timer mode, and Timer interrupt is generated when

timer register T0 (T1) increases and matches TDR0 (TDR1).

This timer interrupt in capture mode is very useful when the pulse width of captured signal is more wider than the maximum period of Timer.

For example, in Figure 12-8 , the pulse width of captured signal is wider than the timer data value (FF_H) over 2 times. When external interrupt is occurred, the captured value (13_H) is more little than wanted value. It can be obtained correct value by counting the number of timer overflow occurrence.

Timer/Counter still does the above, but with the added feature that a edge transition at external input INTx pin causes the current value in the Timer x register (T0,T1), to be cap-

tured into registers CDRx (CDR0, CDR1), respectively. After captured, Timer x register is cleared and restarts by hardware.

It has three transition modes: "falling edge", "rising edge", "both edge" which are selected by interrupt edge selection register IEDS (Refer to External interrupt section). In addition, the transition at INTx pin generate an interrupt.

Note: *The CDRx, TDRx and Tx are in same address. In the capture mode, reading operation is read the CDRx, not Tx because path is opened to the CDRx, and TDRx is only for writing operation.*

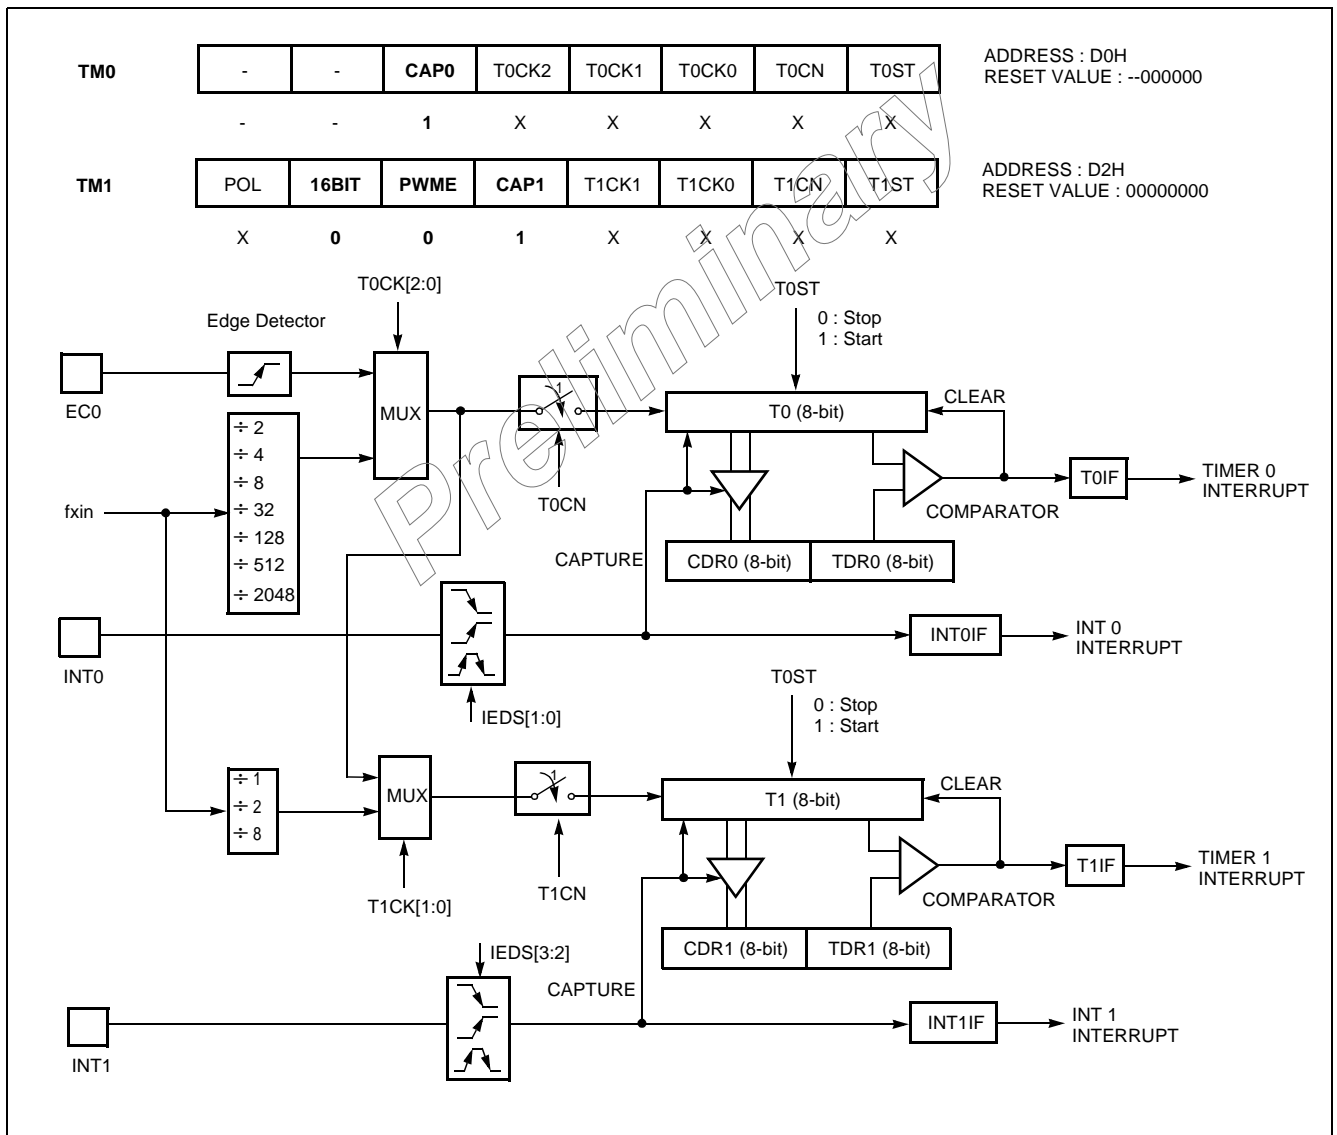

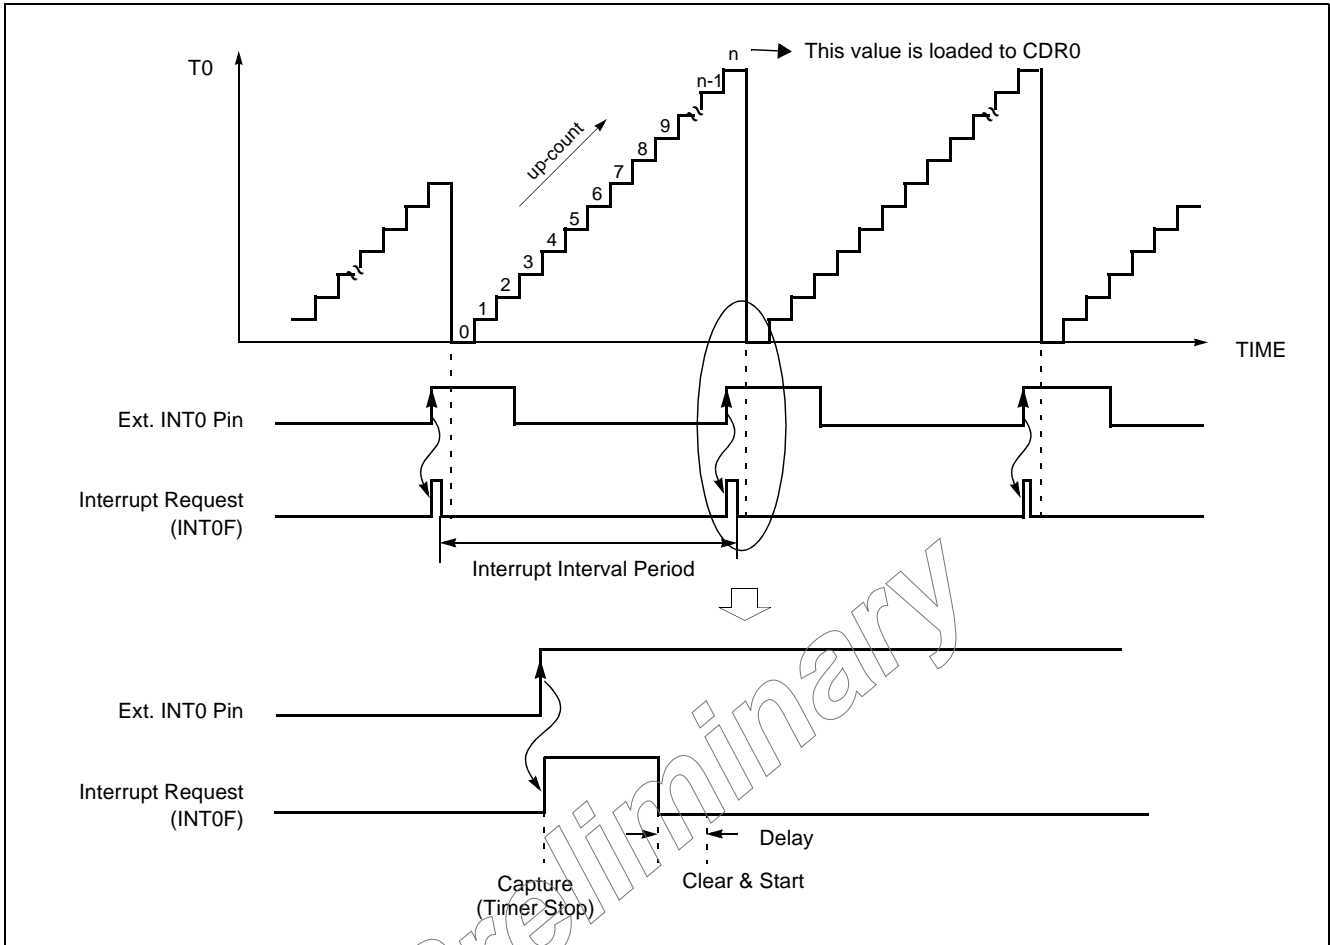

Figure 12-6   8-bit Capture Mode

Interrupt Interval Period = $FF_H + 01_H + FF_H + 01_H + 13_H = 213_H$
Figure 12-8   Excess Timer Overflow in Capture Mode

12.5 16-bit Capture Mode

16-bit capture mode is the same as 8-bit capture, except that the Timer register is being run will 16 bits.

The clock source of the Timer 0 is selected either internal or external clock by bit T0CK2, T0CK1 and T0CK0.

In 16-bit mode, the bits T1CK1,T1CK0 and 16BIT of TM1 should be set to "1" respectively.

Figure 12-9   16-bit Capture Mode

12.6 PWM Mode

The HMS87C1304A and HMS87C1302A has a high speed PWM (Pulse Width Modulation) functions which shared with Timer1.

In PWM mode, pin RB4/COMP0/PWM0 outputs up to a 10-bit resolution PWM output. This pin should be configure as a PWM output by setting "1" bit PWM0O in RB-FUNC register.

The period of the PWM output is determined by the T1PPR (PWM0 Period Register) and PWM0HR[3:2] (bit3,2 of PWM0 High Register) and the duty of the PWM output is determined by the T1PDR (PWM0 Duty Register) and PWM0HR[1:0] (bit1,0 of PWM0 High Register).

The user writes the lower 8-bit period value to the T1PPR and the higher 2-bit period value to the PWM0HR[3:2].

And writes duty value to the T1PDR and the PWM0HR[1:0] same way.

The T1PDR is configure as a double buffering for glitch-less PWM output. In Figure 12-10 , the duty data is transferred from the master to the slave when the period data matched to the counted value. (i.e. at the beginning of next duty cycle)

PWM Period = [PWM0HR[3:2]T1PPR] X Source Clock

PWM Duty = [PWM0HR[1:0]T1PDR] X Source Clock

The relation of frequency and resolution is in inverse proportion. Table 12-2 shows the relation of PWM frequency vs. resolution.

If it needed more higher frequency of PWM, it should be reduced resolution.

Resolution	Frequency		
	T1CK[1:0] = 00(125nS)	T1CK[1:0] = 01(250nS)	T1CK[1:0] = 10(1uS)
10-bit	7.8KHz	3.9KHz	0.98KHZ
9-bit	15.6KHz	7.8KHz	1.95KHz
8-bit	31.2KHz	15.6KHz	3.90KHz
7-bit	62.5KHz	31.2KHz	7.81KHz

Table 12-2 PWM Frequency vs. Resolution at 8MHz

The bit POL of TM1 decides the polarity of duty cycle.

If the duty value is set same to the period value, the PWM output is determined by the bit POL (1: High, 0: Low). And if the duty value is set to "00_H", the PWM output is determined by the bit POL (1: Low, 0: High).

It can be changed duty value when the PWM output. However the changed duty value is output after the current period is over. And it can be maintained the duty value at present output when changed only period value shown as Figure 12-12 . As it were, the absolute duty time is not changed in varying frequency. But the changed period value must greater than the duty value.

Note: *If changing the Timer1 to PWM function, it should be stop the timer clock firstly, and then set period and duty register value. If user writes register values while timer is in operation, these register could be set with certain values.*

13. Buzzer Output function

The buzzer driver consists of 6-bit binary counter, the buzzer register BUR and the clock selector. It generates square-wave which is very wide range frequency (480 Hz~250 KHz at fxin = 4 MHz) by user programmable counter.

Pin RB1 is assigned for output port of Buzzer driver by setting the bit BUZO of RBFUNC to "1".

The 6-bit buzzer counter is cleared and start the counting by writing signal to the register BUR. It is increased from 00H until it matches 6-bit register BUR.

Also, it is cleared by counter overflow and count up to output the square wave pulse of duty 50%.

The bit 0 to 5 of BUR determines output frequency for buzzer driving. Frequency calculation is following as shown below.

$$f_{BUZ}(Hz) = \frac{\text{Oscillator Frequency}}{2 \times \text{Prescaler Ratio} \times (BUR + 1)}$$

The bits BUCK1, BUCK0 of BUR selects the source clock from prescaler output.

Figure 13-1 Buzzer Driver

14. ANALOG TO DIGITAL CONVERTER

The analog-to-digital converter (A/D) allows conversion of an analog input signal to a corresponding 8-bit digital value. The A/D module has eight analog inputs, which are multiplexed into one sample and hold. The output of the sample and hold is the input into the converter, which generates the result via successive approximation.

The analog reference voltage is selected to V_{DD} or AVref by setting of the bit AVREFS in RBFUNC register. If external analog reference AVref is selected, the bit ANSEL0 should not be set to "1", because this pin is used to an analog reference of A/D converter.

The A/D module has two registers which are the control register ADCM and A/D result register ADCR. The ADCM register, shown in Figure 14-2 , controls the operation of the A/D converter module. The port pins can be configure as analog inputs or digital I/O.

To use analog inputs, each port is assigned analog input port by setting the bit ANSEL[7:0] in RAFUNC register. And selected the corresponding channel to be converted by setting ADS[2:0].

The processing of conversion is start when the start bit ADST is set to "1". After one cycle, it is cleared by hardware. The register ADCR contains the results of the A/D conversion. When the conversion is completed, the result is loaded into the ADCR, the A/D conversion status bit ADSF is set to "1", and the A/D interrupt flag ADIF is set. The block diagram of the A/D module is shown in Figure 14-1 . The A/D status bit ADSF is set automatically when A/D conversion is completed, cleared when A/D conversion is in process. The conversion time takes maximum 10 uS (at fxin=8 MHz).

**Figure 14-2 A/D Converter Registers**

Figure 14-3 A/D Converter Operation Flow

A/D Converter Cautions

(1) Input range of AN0 to AN7

The input voltage of AN0 to AN7 should be within the specification range. In particular, if a voltage above VDD (or AVref) or below Vss is input (even if within the absolute maximum rating range), the conversion value for that channel can not be indeterminate. The conversion values of the other channels may also be affected.

(2) Noise countermeasures

In order to maintain 8-bit resolution, attention must be paid to noise on pins AVref(or VDD) and AN0 to AN7. Since the effect increases in proportion to the output impedance of the analog input source, it is recommended that a capacitor be connected externally as shown in Figure 14-4 in order to reduce noise.

Figure 14-4 Analog Input Pin Connecting Capacitor

(3) Pins AN0/RB0 and AN1/RA1 to AN7/RA7

The analog input pins AN0 to AN7 also function as input/output port (PORT RA and RB0) pins. When A/D conversion is performed with any of pins AN0 to AN7 selected, be sure not to execute a PORT input instruction while conversion is in progress, as this may reduce the conversion resolution.

Also, if digital pulses are applied to a pin adjacent to the pin in the process of A/D conversion, the expected A/D conversion value may not be obtainable due to coupling noise. Therefore, avoid applying pulses to pins adjacent to the pin undergoing A/D conversion.

(4) AVref pin input impedance

A series resistor string of approximately 10KΩ is connected between the AVref pin and the Vss pin.

Therefore, if the output impedance of the reference voltage source is high, this will result in parallel connection to the series resistor string between the AVref pin and the Vss pin, and there will be a large reference voltage error.

15. INTERRUPTS

The HMS87C1304A and HMS87C1302A interrupt circuits consist of Interrupt enable register (IENH, IENL), Interrupt request flags of IRQH, IRQL, Interrupt Edge Selection Register (IEDS), priority circuit and Master enable flag("I" flag of PSW). The configuration of interrupt circuit is shown in Figure 15-1 and Interrupt priority is shown in Table 15-1 .

The External Interrupts INT0 and INT1 can each be transition-activated (1-to-0, 0-to-1 and both transition).

The flags that actually generate these interrupts are bit INT0IF and INT1IF in Register IRQH. When an external interrupt is generated, the flag that generated it is cleared

by the hardware when the service routine is vectored to only if the interrupt was transition-activated.

The Timer 0 and Timer 1 Interrupts are generated by T0IF and T1IF, which are set by a match in their respective timer/counter register. The AD converter Interrupt is generated by ADIF which is set by finishing the analog to digital conversion. The Watch dog timer Interrupt is generated by WDTIF which set by a match in Watch dog timer register (when the bit WDTON is set to "0"). The Basic Interval Timer Interrupt is generated by BITIF which is set by a overflowing of the Basic Interval Timer Register(BITR).

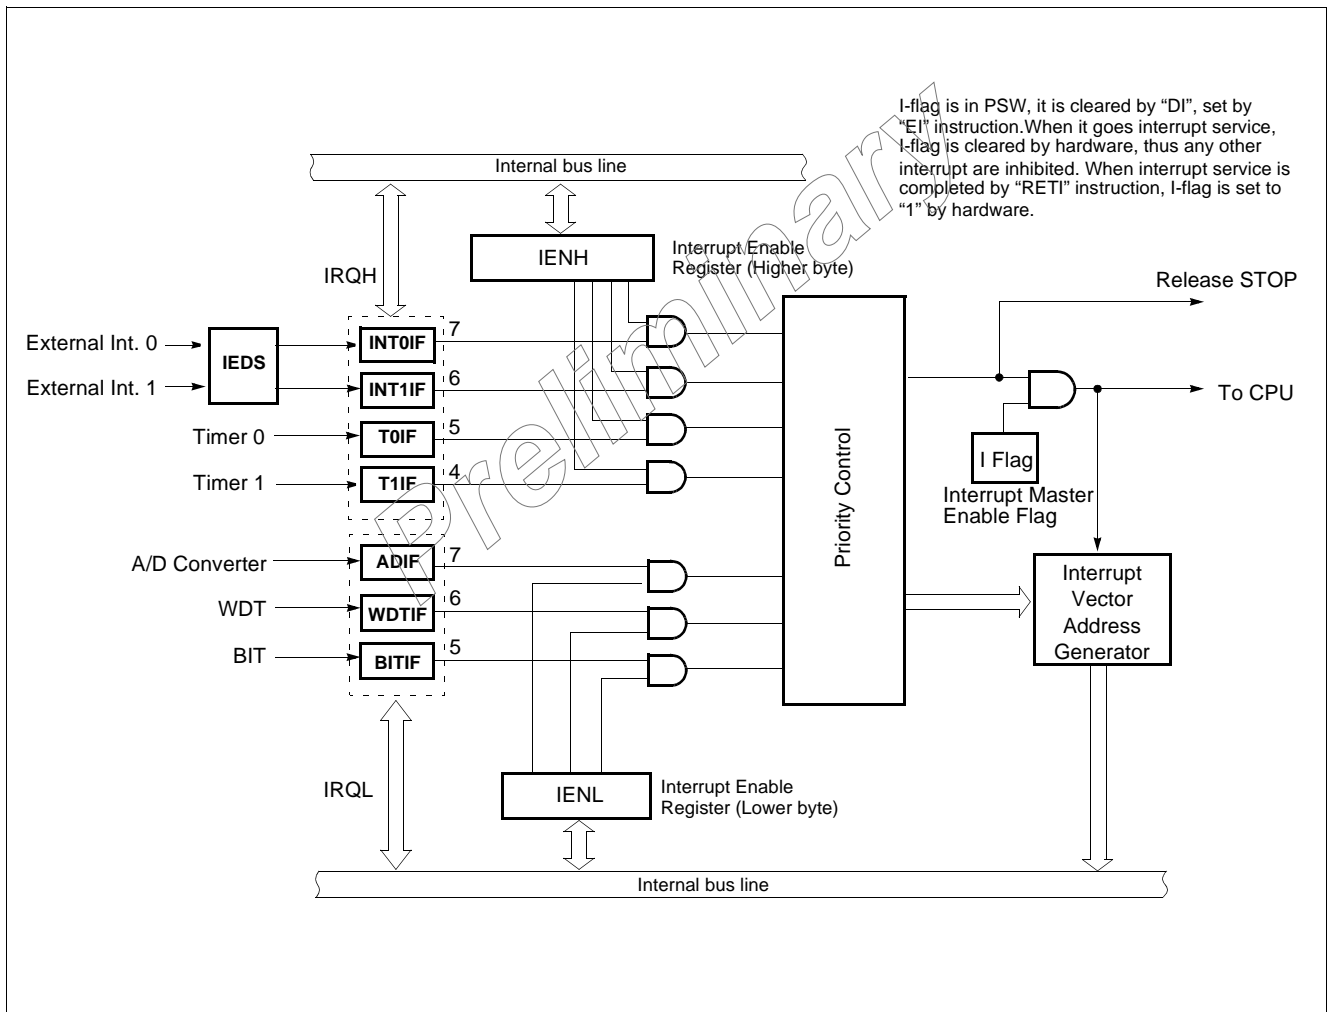

**Figure 15-1 Block Diagram of Interrupt Function**

The interrupts are controlled by the interrupt master enable flag I-flag (bit 2 of PSW), the interrupt enable register (IENH, IENL) and the interrupt request flags (in IRQH, IRQL) except Power-on reset and software BRK interrupt.

Interrupt enable registers are shown in Figure 15-2 . These registers are composed of interrupt enable flags of each interrupt source, these flags determines whether an interrupt will be accepted or not. When enable flag is "0", a corre-

sponding interrupt source is prohibited. Note that PSW contains also a master enable bit, I-flag, which disables all interrupts at once.

0 : Not occurred
1 : Interrupt request is occurred

Figure 15-2   Interrupt Enable Registers and Interrupt Request Registers

When an interrupt is occurred, the I-flag is cleared and disable any further interrupt, the return address and PSW are pushed into the stack and the PC is vectored to. Once in the interrupt service routine the source(s) of the interrupt can be determined by polling the interrupt request flag bits.

15.1 Interrupt Sequence

An interrupt request is held until the interrupt is accepted or the interrupt latch is cleared to "0" by a reset or an instruction. Interrupt acceptance sequence requires 8 f_{OSC} (2

The interrupt request flag bit(s) must be cleared by software before re-enabling interrupts to avoid recursive interrupts. The Interrupt Request flags are able to be read and written.
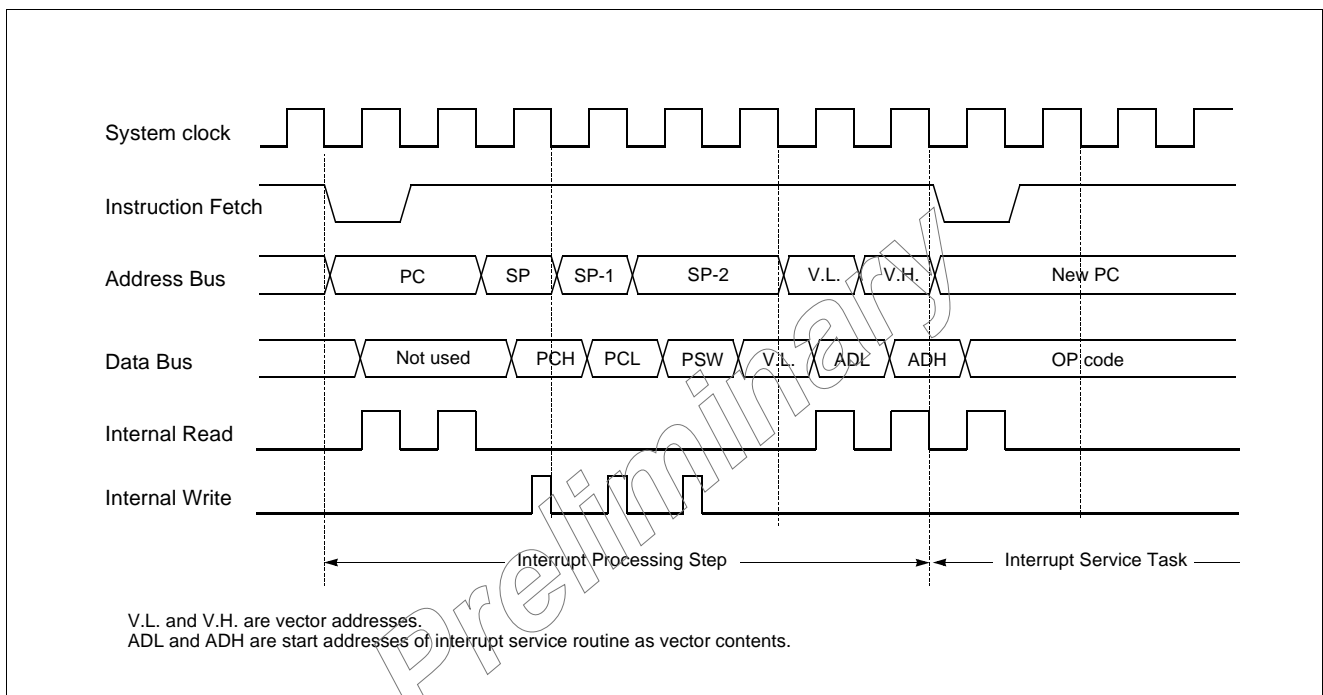

μs at f_{XIN}=4MHz) after the completion of the current instruction execution. The interrupt service task is terminated upon execution of an interrupt return instruction
[RETI].

Interrupt acceptance

1. The interrupt master enable flag (I-flag) is cleared to "0" to temporarily disable the acceptance of any following maskable interrupts. When a non-maskable interrupt is accepted, the acceptance of any following interrupts is temporarily disabled.

2. Interrupt request flag for the interrupt source accepted is cleared to "0".

3. The contents of the program counter (return address) and the program status word are saved (pushed) onto the stack area. The stack pointer decreases 3 times.

4. The entry address of the interrupt service program is read from the vector table address and the entry address is loaded to the program counter.

5. The instruction stored at the entry address of the interrupt service program is executed.

V.L. and V.H. are vector addresses.
ADL and ADH are start addresses of interrupt service routine as vector contents.

Figure 15-3 Timing chart of Interrupt Acceptance and Interrupt Return Instruction

Correspondence between vector table address for BIT interrupt
and the entry address of the interrupt service program.

A interrupt request is not accepted until the I-flag is set to "1" even if a requested interrupt has higher priority than that of the current interrupt being serviced.

When nested interrupt service is required, the I-flag should

be set to "1" by "EI" instruction in the interrupt service program. In this case, acceptable interrupt sources are selectively enabled by the individual interrupt enable flags.

Saving/Restoring General-purpose Register

During interrupt acceptance processing, the program counter and the program status word are automatically saved on the stack, but accumulator and other registers are not saved itself. These registers are saved by the software if necessary. Also, when multiple interrupt services are nested, it is necessary to avoid using the same data memory area for saving registers.

The following method is used to save/restore the general-purpose registers.

Example: Register save using push and pop instructions

```
INTxx:   PUSH    A       ;SAVE ACC.
         PUSH    X       ;SAVE X REG.
         PUSH    Y       ;SAVE Y REG.

         ┌─────────────────────────┐
         │  interrupt processing   │
         └─────────────────────────┘

         POP     Y       ;RESTORE Y REG.
         POP     X       ;RESTORE X REG.
         POP     A       ;RESTORE ACC.
         RETI            ;RETURN
```

General-purpose register save/restore using push and pop instructions;

15.2 BRK Interrupt

Software interrupt can be invoked by BRK instruction, which has the lowest priority order.

Interrupt vector address of BRK is shared with the vector of TCALL 0 (Refer to Program Memory Section). When BRK interrupt is generated, B-flag of PSW is set to distinguish BRK from TCALL 0.

Each processing step is determined by B-flag as shown in Figure 15-4 .
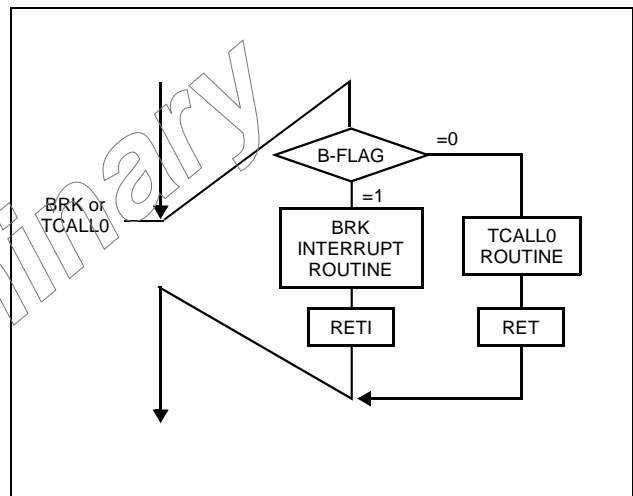

Figure 15-4   Execution of BRK/TCALL0

15.3 Multi Interrupt

If two requests of different priority levels are received simultaneously, the request of higher priority level is serviced. If requests of the interrupt are received at the same time simultaneously, an internal polling sequence determines by hardware which request is serviced.

However, multiple processing through software for special features is possible. Generally when an interrupt is accepted, the I-flag is cleared to disable any further interrupt. But as user sets I-flag in interrupt routine, some further interrupt can be serviced even if certain interrupt is in progress.
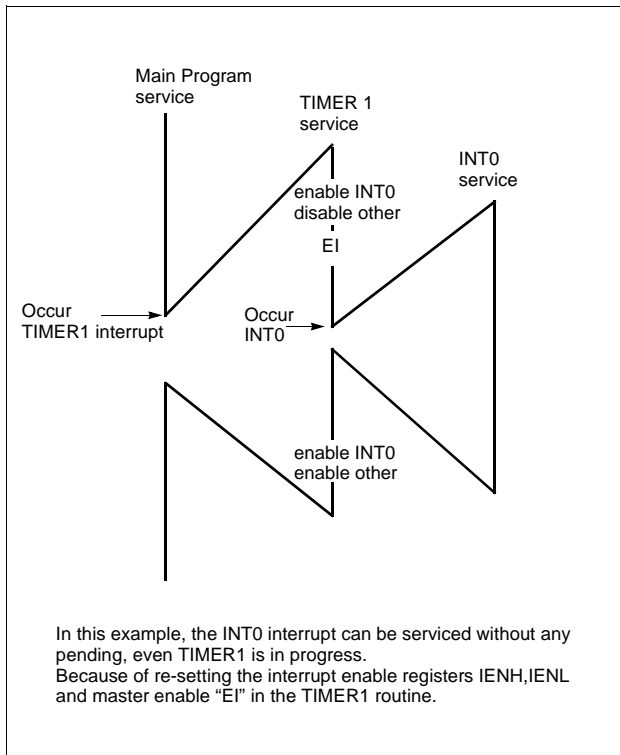

Example: Even though Timer1 interrupt is in progress, INT0 interrupt serviced without any suspend.

```
TIMER1:   PUSH   A
          PUSH   X
          PUSH   Y
          LDM    IENH,#80H    ;Enable INT0 only
          LDM    IENL,#0      ;Disable other
          EI                  ;Enable Interrupt
          :
          :
          :

          :
          :
          :
          LDM    IENH,#0F0H   ;Enable all interrupts
          LDM    IENL,#0E0H
          POP    Y
          POP    X
          POP    A
          RETI
```

In this example, the INT0 interrupt can be serviced without any pending, even TIMER1 is in progress.
Because of re-setting the interrupt enable registers IENH,IENL and master enable "EI" in the TIMER1 routine.

Figure 15-5 Execution of Multi Interrupt

15.4 External Interrupt

The external interrupt on INT0 and INT1 pins are edge triggered depending on the edge selection register IEDS (address 0E6$_H$) as shown in Figure 15-6 .

The edge detection of external interrupt has three transition activated mode: rising edge, falling edge, and both edge.
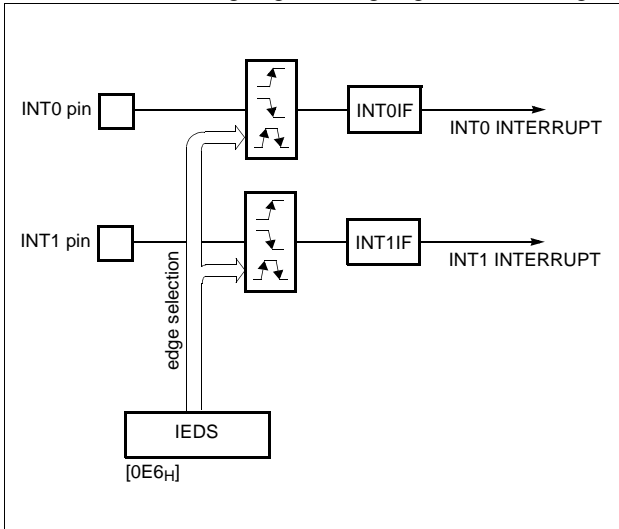

Figure 15-6 External Interrupt Block Diagram

        :
        :
        :
```

Response Time

The INT0 and INT1 edge are latched into INT0IF and INT1IF at every machine cycle. The values are not actually polled by the circuitry until the next machine cycle. If a request is active and conditions are right for it to be acknowledged, a hardware subroutine call to the requested service routine will be the next instruction to be executed. The DIV itself takes twelve cycles. Thus, a minimum of twelve complete machine cycles elapse between activation of an external interrupt request and the beginning of execution of the first instruction of the service routine.
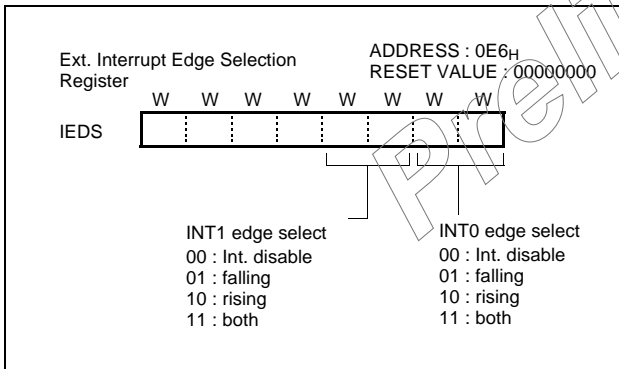

shows interrupt response timings.

Figure 15-7 Interrupt Response Timing Diagram

Preliminary

16. WATCHDOG TIMER

The purpose of the watchdog timer is to detect the malfunction (runaway) of program due to external noise or other causes and return the operation to the normal condition.

The watchdog timer has two types of clock source.

The first type is an on-chip RC oscillator which does not require any external components. This RC oscillator is separate from the external oscillator of the Xin pin. It means that the watchdog timer will run, even if the clock on the Xin pin of the device has been stopped, for example, by entering the STOP mode.

The other type is a prescaled system clock.

The watchdog timer consists of 7-bit binary counter and the watchdog timer data register. When the value of 7-bit binary counter is equal to the lower 7 bits of WDTR, the interrupt request flag is generated. This can be used as WDT interrupt or reset the CPU in accordance with the bit WDTON.

Note: *Because the watchdog timer counter is enabled after clearing Basic Interval Timer, after the bit WDTON set to "1", maximum error of timer is depend on prescaler ratio of Basic Interval Timer.*

The 7-bit binary counter is cleared by setting WDTCL(bit7 of WDTR) and the WDTCL is cleared automatically after 1 machine cycle.

The RC oscillated watchdog timer is activated by setting the bit RCWDT as shown below.

```
  :
LDM      CKCTLR,#3FH   ; enable the RC-osc WDT
LDM      WDTR,#0FFH    ; set the WDT period
STOP                   ; enter the STOP mode
NOP
NOP                    ; RC-osc WDT running
  :
```

The RC oscillation period is vary with temperature, V_{DD} and process variations from part to part (approximately, 40~120uS). The following equation shows the RC oscillated watchdog timer time-out.

$$T_{RCWDT} = CLK_{RC} \times 2^8 \times [WDTR.6{\sim}0] + (CLK_{RC} \times 2^8)/2$$

$$where, \; CLK_{RC} = 40{-}120uS$$

In addition, this watchdog timer can be used as a simple 7-bit timer by interrupt WDTIF. The interval of watchdog timer interrupt is decided by Basic Interval Timer. Interval equation is as below.

$$T_{WDT} = [WDTR.6{\sim}0] \times Interval \; of \; BIT$$

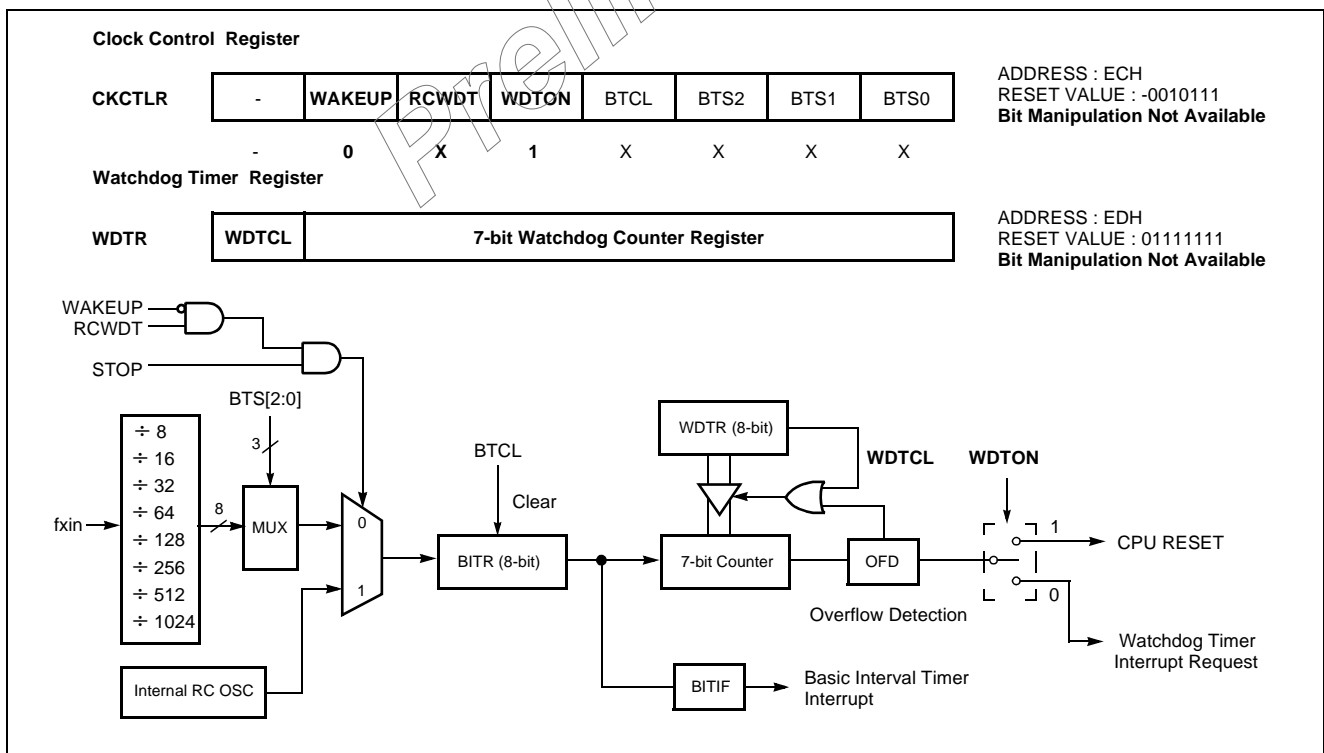

Figure 16-1 Block Diagram of Watchdog Timer

17. Power Saving Mode

For applications where power consumption is a critical factor, device provides three kinds of power saving functions, STOP mode, Wake-up Timer mode and internal RC-oscillated watchdog timer mode.

The power saving function is activated by execution of STOP instruction after setting the corresponding bit (WAKEUP, RCWDT) of CKCTLR.

Table 17-1 shows the status of each Power Saving Mode

*Note: **Before executing STOP instruction, clear all interrupt request flag.** Because if the interrupt request flag is set before STOP instruction, the MCU runs as if it doesn't perform STOP instruction, even though the STOP instruction is completed. So insert two lines to clear all interrupt request flags (IRQH, IRQL) before STOP instruction as shown each example.*

Peripheral	STOP	Wake-up Timer	Internal RC-WDT
RAM	Retain	Retain	Retain
Control Registers	Retain	Retain	Retain
I/O Ports	Retain	Retain	Retain
CPU	Stop	Stop	Stop
Timer0	Stop	Operation	Stop
Oscillation	Stop	Oscillation	Stop
Prescaler	Stop	÷ 2048 only	Stop
Internal RC oscillator	Stop	Stop	Oscillation
Entering Condition CKCTLR[6,5]	00	1X	01
Power Saving Release Source	RESET, INT0, INT1	RESET, INT0, INT1, Timer0	RESET, INT0, INT1, RC-WDT

Table 17-1 Power Saving Mode

17.1 Stop Mode

In the Stop mode, the on-chip oscillator is stopped. With the clock frozen, all functions are stopped, but the on-chip RAM and Control registers are held. The port pins out the values held by their respective port data register, port direction registers. Oscillator stops and the systems internal operations are all held up.

- The states of the RAM, registers, and latches valid immediately before the system is put in the STOP state are all held.
- The program counter stop the address of the instruction to be executed after the instruction "STOP" which starts the STOP operating mode.

The Stop mode is activated by execution of STOP instruction after setting the bit WAKEUP and RCWDT of CKCTLR to "00". (This register should be written by byte operation. If this register is set by bit manipulation instruction, for example "set1" or "clr1" instruction, it may be undesired operation)

In the Stop mode of operation, V_{DD} can be reduced to minimize power consumption. Care must be taken, however, to ensure that V_{DD} is not reduced before the Stop mode is invoked, and that V_{DD} is restored to its normal operating level, before the Stop mode is terminated.

The reset should not be activated before V_{DD} is restored to its normal operating level, and must be held active long enough to allow the oscillator to restart and stabilize.

Note: After STOP instruction, at least two or more NOP instruction should be written

```
Ex)   LDM CKCTLR,#0000_1110B
      LDM IRQH,#0
      LDM IRQL,#0
      STOP
      NOP
      NOP
```

In the STOP operation, the dissipation of the power associated with the oscillator and the internal hardware is lowered; however, the power dissipation associated with the pin interface (depending on the external circuitry and program) is not directly determined by the hardware operation

of the STOP feature. This point should be little current flows when the input level is stable at the power voltage level (V_{DD}/V_{SS}), however, when the input level gets higher than the power voltage level (by approximately 0.3 to 0.5V), a current begins to flow. Therefore, if cutting off the output transistor at an I/O port puts the pin signal into the high-impedance state, a current flow across the ports input transistor, requiring to fix the level by pull-up or other means.

Release the STOP mode

The exit from STOP mode is hardware reset or external interrupt. Reset re-defines all the Control registers but does not change the on-chip RAM. External interrupts allow both on-chip RAM and Control registers to retain their values.

After releasing STOP mode, instruction execution is divided into two ways by I-flag(bit2 of PSW).
If I-flag = 1, the normal interrupt response takes place. If I-flag = 0, the chip will resume execution starting with the instruction following the STOP instruction. It will not vector to interrupt service routine. (refer to)

When exit from Stop mode by external interrupt, enough oscillation stabilization time is required to normal operation. shows the timing diagram. When release the Stop mode, the Basic interval timer is activated on wake-up. It is increased from 00_H until FF_H. The count overflow is set to start normal operation. Therefore, before STOP instruction, user must be set its relevant prescaler divide ratio to have long enough time (more than 20msec). This guarantees that oscillator has started and stabilized.

By reset, exit from Stop mode is shown in .

Minimizing Current Consumption in Stop Mode

The Stop mode is designed to reduce power consumption.

To minimize the current consumption during Stop mode, the user should turn-off output drivers that are sourcing or sinking current, if it is practical. Weak pull-ups on port pins should be turned off, if possible. All inputs should be either as V_{SS} or at V_{DD} (or as close to rail as possible).

An intermediate voltage on an input pin causes the input buffer to draw a significant amount of current.

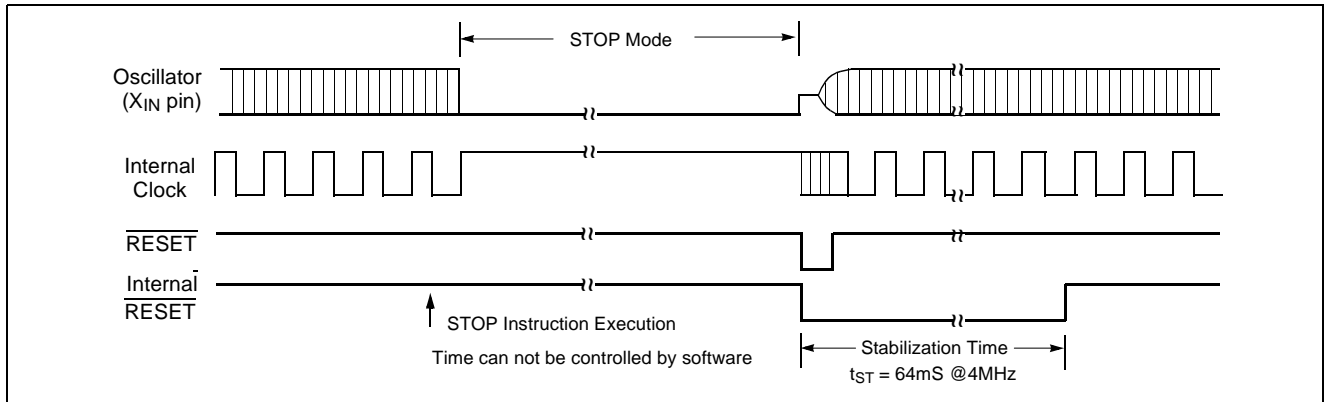

Figure 17-1   STOP Releasing Flow by Interrupts

Figure 17-2   Timing of STOP Mode Release by External Interrupt

Figure 17-3   Timing of STOP Mode Release by RESET

17.2 Wake-up Timer Mode

In the Wake-up Timer mode, the on-chip oscillator is not stopped. Except the Prescaler (only 2048 divided ratio) and Timer0, all functions are stopped, but the on-chip RAM and Control registers are held. The port pins out the values held by their respective port data register, port direction registers.

The Wake-up Timer mode is activated by execution of STOP instruction after setting the bit WAKEUP of CKCTLR to "1". (This register should be written by byte operation. If this register is set by bit manipulation instruction, for example "set1" or "clr1" instruction, it may be undesired operation)

Note: *After STOP instruction, at least two or more NOP instruction should be written*

```
Ex)  LDM  TDR0,#0FFH
     LDM  TM0,#0001_1011B
     LDM  CKCTLR,#0100_1110B
     LDM  IRQH,#0
     LDM  IRQL,#0
     STOP
     NOP
     NOP
```

In addition, the clock source of timer0 should be selected to 2048 divided ratio. Otherwise, the wake-up function can not work. And the timer0 can be operated as 16-bit timer with timer1 (refer to timer function). The period of wake-up function is varied by setting the timer data register 0, TDR0.

Release the Wake-up Timer mode

The exit from Wake-up Timer mode is hardware reset, Timer0 overflow or external interrupt. Reset re-defines all the Control registers but does not change the on-chip RAM. External interrupts and Timer0 overflow allow both on-chip RAM and Control registers to retain their values.

If I-flag = 1, the normal interrupt response takes place. If I-flag = 0, the chip will resume execution starting with the instruction following the STOP instruction. It will not vector to interrupt service routine (refer to).

When exit from Wake-up Timer mode by external interrupt or timer0 overflow, the oscillation stabilization time is not required to normal operation. Because this mode do not stop the on-chip oscillator shown as .
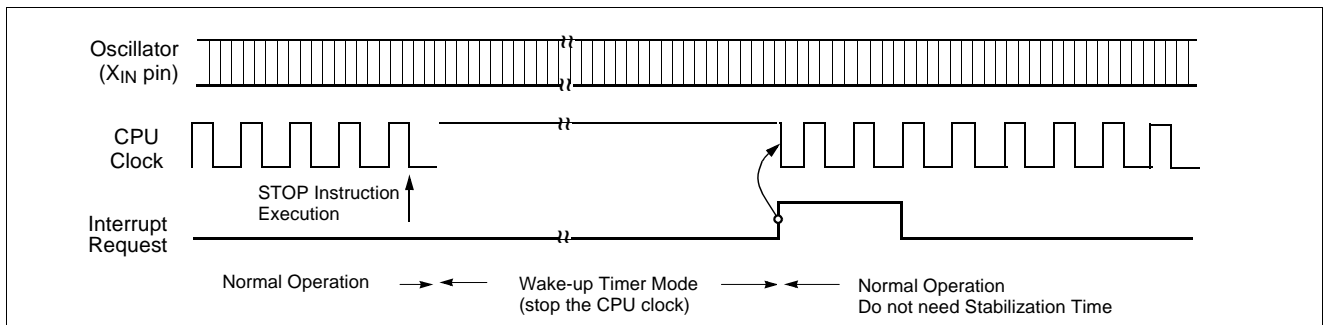

Figure 17-4   Wake-up Timer Mode Releasing by External Interrupt or Timer0 Interrupt

17.3 Internal RC-Oscillated Watchdog Timer Mode

In the Internal RC-Oscillated Watchdog Timer mode, the on-chip oscillator is stopped. But internal RC oscillation circuit is oscillated in this mode. The on-chip RAM and Control registers are held. The port pins out the values held by their respective port data register, port direction registers.

The Internal RC-Oscillated Watchdog Timer mode is activated by execution of STOP instruction after setting the bit WAKEUP and RCWDT of CKCTLR to "01". (This register should be written by byte operation. If this register is set by bit manipulation instruction, for example "set1" or "clr1" instruction, it may be undesired operation)

Note: *After STOP instruction, at least two or more NOP instruction should be written*

```
Ex)   LDM   WDTR,#1111_1111B
      LDM   CKCTLR,#0010_1110B
      LDM   IRQH,#0
      LDM   IRQL,#0
      STOP
      NOP
      NOP
```

Release the Internal RC-Oscillated Watchdog Timer mode

The exit from Internal RC-Oscillated Watchdog Timer mode is hardware reset or external interrupt. Reset re-de-fines all the Control registers but does not change the on-chip RAM. External interrupts allow both on-chip RAM and Control registers to retain their values.

If I-flag = 1, the normal interrupt response takes place. In this case, if the bit WDTON of CKCTLR is set to "0" and the bit WDTE of IENH is set to "1", the device will execute the watchdog timer interrupt service routine.() However, if the bit WDTON of CKCTLR is set to "1", the device will generate the internal RESET signal and execute the reset processing. ()

If I-flag = 0, the chip will resume execution starting with the instruction following the STOP instruction. It will not vector to interrupt service routine (refer to).

When exit from Internal RC-Oscillated Watchdog Timer mode by external interrupt, the oscillation stabilization time is required for normal operation. shows the timing diagram. When release the Internal RC-Oscillated Watchdog Timer mode, the basic interval timer is activated on wake-up. It is increased from 00_H until FF_H. The count overflow is set to start normal operation. Therefore, before STOP instruction, user must be set its relevant prescaler divide ratio to have long enough time (more than 20msec). This guarantees that oscillator has started and stabilized.

By reset, exit from internal RC-Oscillated Watchdog Timer mode is shown in .

**Figure 17-6   Internal RCWDT Mode Releasing by RESET.**

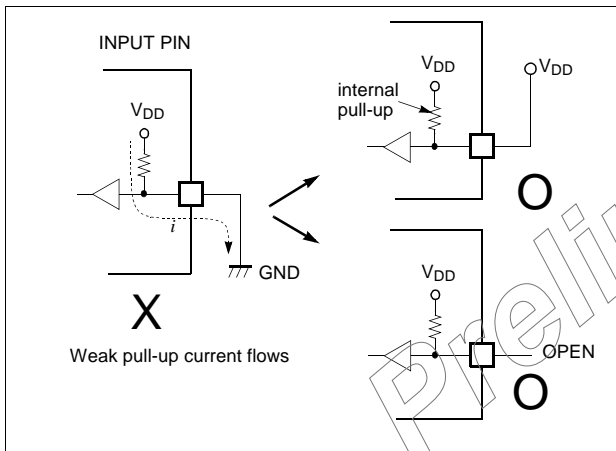

Figure 17-7 Application Example of Unused Input Port

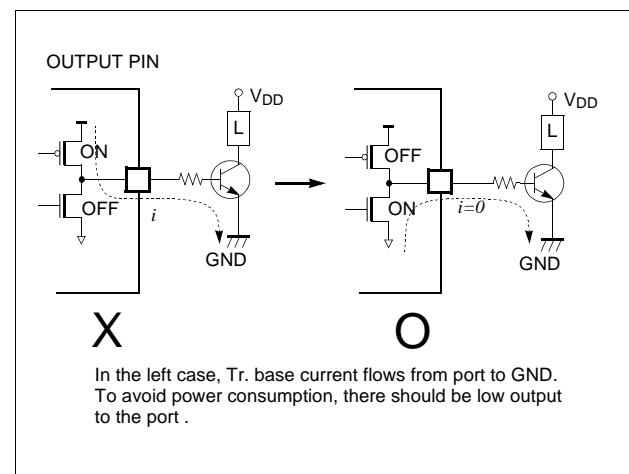

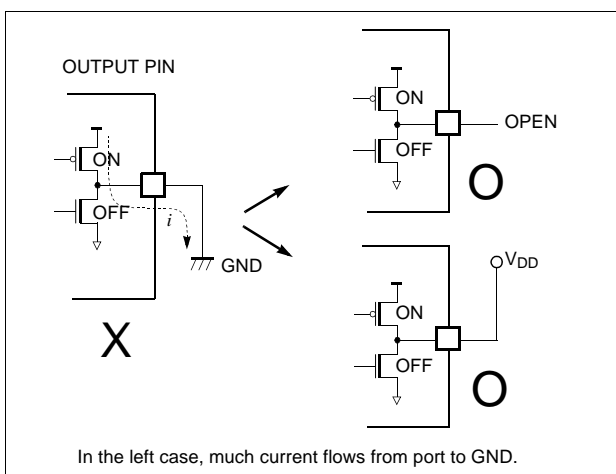

Figure 17-8 Application Example of Unused input Port

18. RESET

The reset input is the RESET pin, which is the input to a Schmitt Trigger. A reset in accomplished by holding the RESET pin low for at least 8 oscillator periods, while the oscillator running. After reset, 64ms (at 4 MHz) add with 7 oscillator periods are required to start execution as shown in Figure 18-1 .

Internal RAM is not affected by reset. When V_{DD} is turned on, the RAM content is indeterminate. Therefore, this RAM should be initialized before reading or testing it.

Initial state of each register is shown as Table 8-1 .
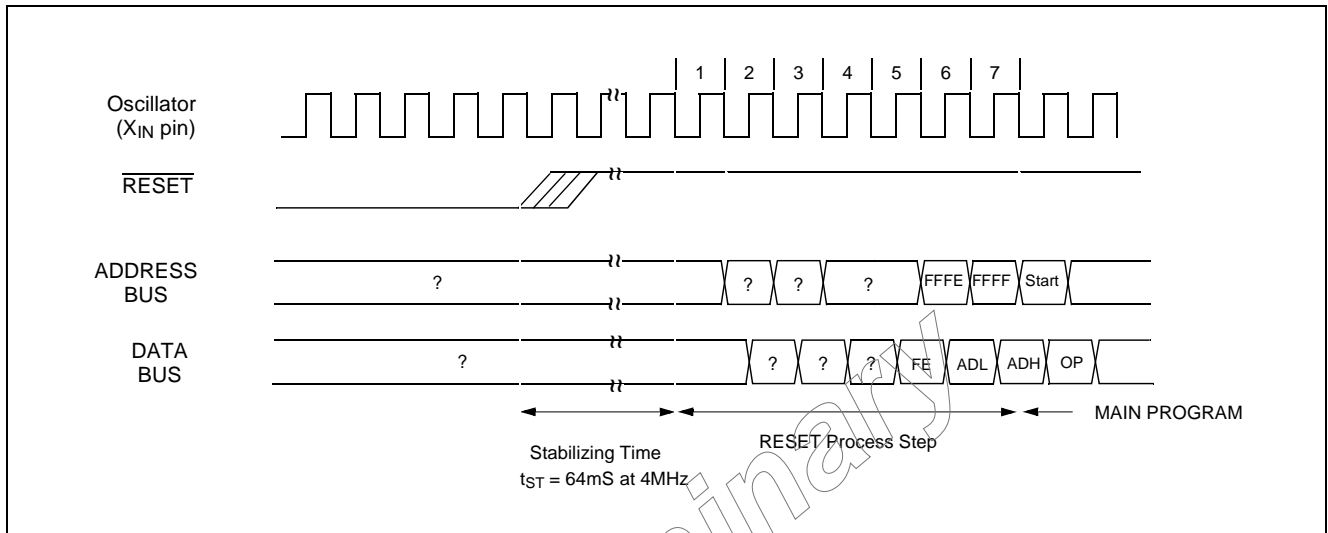

Figure 18-1 Timing Diagram after RESET

19. POWER FAIL PROCESSOR

The HMS87C1304A and HMS87C1302A has an on-chip power fail detection circuitry to immunize against power noise. A configuration register, PFDR, can enable (if clear/programmed) or disable (if set) the Power-fail Detect circuitry. If V_{DD} falls below 2.5~3.5V(2.0~3.0V) range for longer than 50 nS, the Power fail situation may reset MCU according to PFS bit of PFDR. And power fail detect level is selectable by mask option. On the other hand, in the OTP, power fail detect level is decided by setting the bit PFDLEVEL of CONFIG register when program the OTP.

As below PFDR register is not implemented on the in-cir-

cuit emulator, user can not experiment with it. Therefore, after final development of user program, this function may be experimented.

Note: *Power fail detect level is decided by mask option checking the bit PFDLEVEL of MASK ORDER SHEET (refer to MASK ORDER SHEET)*
In thc case of OTP, Power fail detect level is decided by setting the bit PFDLEVEL of CONFIG register (refer to Figure 20-1 .

Figure 19-3 Power Fail Processor Situations

20. DEVICE CONFIGURATION AREA

The Device Configuration Area can be programmed or left unprogrammed to select device configuration such as security bit.

Ten memory locations ($0F50_H$ ~ $0FE0_H$) are designated as

Customer ID recording locations where the user can store check-sum or other customer identification numbers.
This area is not accessible during normal execution but is readable and writable during program / verify.
