

HT82K68E

Multimedia Keyboard Encoder 8-Bit OTP MCU

### **Technical Document**

- <u>Tools Information</u>
- <u>FAQs</u>
- <u>Application Note</u>

### Features

- Operating voltage: 2.2V~5.5V
- 32/34 bidirectional I/O lines
- One 8-bit programmable timer counter with overflow interrupts
- Crystal or RC oscillator
- Watchdog Timer
- 3K×16 program EPROM
- 160×8 data RAM
- One external interrupt pin (shared with PC2)

### **General Description**

The HT82K68E is an 8-bit high performance peripheral interface IC, designed for multiple I/O products and multimedia applications. It supports interface to a low speed PC with multimedia keyboard or wireless keyboard in

- 2.4V LVR by option (default disable)
- HALT function and wake-up feature reduce power consumption
- Six-level subroutine nesting
- Bit manipulation instructions
- 16-bit table read instructions
- 63 powerful instructions
- All instructions in 1 or 2 machine cycles
- 20/28-pin SOP, 48-pin SSOP package

Windows 95, Windows 98 or Windows 2000 environment. A HALT feature is included to reduce power consumption.

### **Pin Description**

Pin Name	I/O	Mask Option	Description
PA0~PA7	I/O	Wake-up Pull-high or None	Bidirectional 8-bit input/output port. Each bit can be configured as a wake-up input by mask option. Software* instructions determine the CMOS output or Schmitt Trigger input with or without 12K pull-high resistor.
PB0~PB7	I/O	Pull-high or None	Bidirectional 8-bit input/output port. Software* instructions determine the output or Schmitt Trigger input with or without pull-high resistor.
PC0	I/O	Wake-up Pull-high or None	This pin is an I/O port. NMOS open drain output with pull-high resistor and can be used as DATA or CLOCK line of PS2. This pin can be configured as a wake-up in- put by mask option.
PC1	I/O	Wake-up Pull-high or None	This pin is an I/O port. NMOS open drain output with pull-high resistor and can be used as DATA or CLOCK line of PS2. This pin can be configured as a wake-up in- put by mask option.
PC2~PC3	I/O	Wake-up Pull-high or None	Bidirectional 2-bit input/output port. Each bit can be configured as a wake-up input by mask option. Software* instructions determine the CMOS output or Schmitt Trigger input with or without pull-high resistor. PC2 also as external interrupt input pin. PE0 determine whether rising edge or fall- ing edge of PC2 to trigger the INT circuit.
PC4~PC7	I/O	Pull-high or None	Bidirectional 4-bit input/output port. Software* instructions determine the CMOS output or Schmitt Trigger input with or without pull-high resistor.
PD0~PD7	I/O	Pull-high or None	Bidirectional 8-bit input/output port. Software* instructions determine the CMOS output or Schmitt Trigger input with or without pull-high resistor.

Pin Name	I/O	Mask Option	Description
PE0~PE1	I/O	Pull-high or None	Bidirectional input/output port. Software* instruction determine the CMOS output or Schmitt Trigger input with or without pull-high resistor. If PE0 output 1, rising edge of PC2 trigger INT circuit. PE0 output 0, falling edge of PC2 trigger INT circuit.
PE2	0		This pin is a CMOS output structure. The pad can function as LED (SCR) drivers for the keyboard. $I_{OL}{=}18mA$ at $V_{OL}{=}3.4V$
PE3	0		This pin is a CMOS output structure. The pad can function as LED (NUM) drivers for the keyboard. $I_{OL}{=}18mA$ at $V_{OL}{=}3.4V$
PE4	0		This pin is a CMOS output structure. The pad can function as LED (CAP) drivers for the keyboard. $I_{OL}$ =18mA at $V_{OL}$ =3.4V
VDD	—		Positive power supply
VSS			Negative power supply, ground
RESET	I	_	Chip reset input. Active low. Built-in power-on reset circuit to reset the entire chip. Chip can also be externally reset via RESET pin
OSC1 OSC2	І О	Crystal or RC	OSC1, OSC2 are connected to an RC network or a crystal for the internal system clock. In the case of RC operation, OSC2 is the output terminal for the 1/4 system clock; A 110k $\Omega$ resistor is connected to OSC1 to generate a 2 MHZ frequency.

Note: \*: Software means the HT–IDE (Holtek Integrated Development Environment) can be configured by mask option.

### **Absolute Maximum Ratings**

Supply VoltageV_SS-0.3V to V_SS+6.0V	Storage Temperature–50°C to 125°C
Input VoltageV_SS^=0.3V to V_DD^+0.3V	Operating Temperature25°C to 70°C

Note: These are stress ratings only. Stresses exceeding the range specified under "Absolute Maximum Ratings" may cause substantial damage to the device. Functional operation of this device at other conditions beyond those listed in the specification is not implied and prolonged exposure to extreme conditions may affect device reliability.

### **Functional Description**

#### **Execution Flow**

The HT82K68E system clock is derived from either a crystal or an RC oscillator. The system clock is internally divided into four non-overlapping clocks. One instruction cycle consists of four system clock cycles.

Instruction fetching and execution are pipelined in such a way that a fetch takes one instruction cycle while decoding and execution takes the next instruction cycle. However, the pipelining scheme causes each instruction to effectively execute within one cycle. If an instruction changes the program counter, two cycles are required to complete the instruction.

#### **Program Counter – PC**

The 12-bit program counter (PC) controls the sequence in which the instructions stored in the program ROM are executed and its contents specify a maximum of 4096 addresses.

After accessing a program memory word to fetch an instruction code, the contents of the program counter are incremented by one. The program counter then points to the memory word containing the next instruction code. When executing a jump instruction, conditional skip execution, loading PCL register, subroutine call, initial reset, internal interrupt, external interrupt or return from subroutine, the PC manipulates the program transfer by loading the address corresponding to each instruction.

The conditional skip is activated by instruction. Once the condition is met, the next instruction, fetched during the current instruction execution, is discarded and a dummy cycle replaces it to get the proper instruction. Otherwise proceed with the next instruction.

The lower byte of the program counter (PCL) is a readable and writeable register (06H). Moving data into the PCL performs a short jump. The destination will be within 256 locations.

Once a control transfer takes place, an additional dummy cycle is required.

#### **Program Memory – ROM**

The program memory is used to store the program instructions which are to be executed. It also contains data, table, and interrupt entries, and is organized with  $3072 \times 16$  bits, addressed by the program counter and table pointer.

#### **Execution Flow**

Mada		Program Counter										
Mode	*11	*10	*9	*8	*7	*6	*5	*4	*3	*2	*1	*0

#11~#0: Instruction code bits

S11~S0: Stack register bits @7~@0: PCL bits

#### **Program Memory**

Certain locations in the program memory are reserved for special usage:

• Location 000

This area is reserved for the initialization program. After chip reset, the program always begins execution at location 000H.

Location 004H

Location 004H is reserved for external interrupt service program. If the PC2 (external input pin) is activated, the interrupt is enabled, and the stack is not full, the program begins execution at location 004H. The pin PE0 determine whether the rising or falling edge of the PC2 to activate external interrupt service program.

Location 008H

This area is reserved for the timer counter interrupt service program. If timer interrupt results from a timer counter overflow, and if the interrupt is enabled and the stack is not full, the program begins execution at location 008H.

Table location

Any location in the ROM space can be used as look-up tables. The instructions TABRDC [m] (the current page, one page=256 words) and TABRDL [m] (the last page) transfer the contents of the lower-order byte to the specified data memory, and the higher-order byte to TBLH (08H). Only the destination of the lower-order byte in the table is well-defined, the other bits of the table word are transferred to the lower portion of TBLH, the remaining 1 bit is read as 0. The Table Higher-order byte register (TBLH) is read only. The TBLH is read only and cannot be restored. If the main routine and the ISR (Interrupt Service Routine) both employ the table read instruction, the contents of the TBLH in the main routine are likely to be changed by the table read instruction used in the ISR. Errors can occur. In other words, using the table read instruction in the main routine and the ISR simultaneously should be avoided. However, if the table read instruction has to be applied in both the main routine and the ISR, the interrupt is supposed to be disabled prior to the table read instruction. It will not be enabled until the TBLH has been backed up. The table pointer (TBLP) is a read/write register (07H), which indicates the table location. Before accessing the table, the location must be placed in TBLP. All table related instructions need 2 cycles to complete the operation. These areas may function as normal program memory depending upon the requirements.

#### Stack Register – STACK

This is a special part of the memory which is used to save the contents of the program counter (PC) only. The stack is organized into six levels and is neither part of the data nor part of the program space, and is neither readable nor writeable. The activated level is indexed by the stack pointer (SP) and is neither readable nor writeable. At a subroutine call or interrupt acknowledgement, the contents of the program counter are pushed onto the stack. At the end of a subroutine or an interrupt routine, signaled by a return instruction (RET or RETI), the program counter is restored to its previous value from the stack. After a chip reset, the SP will point to the top of the stack.

#### Data Memory – RAM

The data memory is designed with  $184 \times 8$  bits. It is divided into two functional groups: special function registers and general purpose data memory ( $160 \times 8$ ). Most of them are read/write, but some are read only.

The special function registers include the Indirect Addressing register 0 (00H), the Memory Pointer register 0 (MP0;01H), the Indirect Addressing register 1 (02H), the Memory Pointer register 1 (MP1;03H), the Accumulator (ACC;05H), the Program Counter Lower-byte register (PCL;06H), the Table Pointer (TBLP;07H), the Table Higher-order byte register (TBLH;08H), the Watchdog Timer option Setting register (WDTS;09H), the Status register (STATUS;0AH), the Interrupt Control register

#### **RAM Mapping**

(INTC;0BH), the timer counter register (TMR;0DH), the timer counter control register (TMRC;0EH), the I/O registers (PA;12H, PB;14H, PC;16H, PD;18H, PE;1AH) and the I/O control registers (PAC;13H, PBC;15H, PCC;17H, PDC;19H, PEC;1BH). The remaining space before the 60H is reserved for future expanded usage and reading these locations will get the result 00H. The general purpose data memory, addressed from 60H to FFH, is used for data and control information under instruction command.

All data memory areas can handle arithmetic, logic, increment, decrement and rotate operations directly. Except for some dedicated bits, each bit in the data memory can be set and reset by the SET [m].i and CLR [m].i instructions, respectively. They are also indirectly accessible through Memory pointer registers (MP0;01H, MP1;03H).

#### Indirect Addressing Register

Location 00H and 02H are indirect addressing registers that are not physically implemented. Any read/write operation of [00H] and [02H] can access the data memory pointed to by MP0 (01H) and MP1 (03H) respectively. Reading location 00H or 02H indirectly will return the result 00H. Writing indirectly results in no operation.

The function of data movement between two indirect addressing registers is not supported. The memory pointer registers, MP0 and MP1, are 8-bit registers which can be used to access the data memory by combining corresponding indirect addressing registers.

#### Accumulator

The accumulator is closely related to the ALU operations. It is also mapped to location 05H of the data memory and is capable of carrying out immediate data operations. The data movement between two data memory locations must pass through the accumulator.

#### Arithmetic and Logic Unit – ALU

This circuit performs 8-bit arithmetic and logic operation. The ALU provides the following functions:

- Arithmetic operations (ADD, ADC, SUB, SBC, DAA)
- Logic operations (AND, OR, XOR, CPL)
- Rotation (RL, RR, RLC, RRC)
- Increment and Decrement (INC, DEC)
- Branch decision (SZ, SNZ, SIZ, SDZ ....)

The ALU not only saves the results of a data operation but also changes the status register.

#### Status Register - Status

The 8-bit status register (0AH) contains the zero flag (Z), carry flag (C), auxiliary carry flag (AC), overflow flag (OV), power down flag (PDF) and watch dog time-out flag (TO). The status register not only records the status information but also controls the operation sequence.

With the exception of the TO and PDF flags, bits in the status register can be altered by instructions like most other registers. Any data written into the status register will not change the TO or PDF flags. It should be noted that operations related to the status register may give different results from those intended. The TO and PDF flags can only be changed by system power up, Watch-dog Timer overflow, executing the HALT instruction and clearing the Watchdog Timer.

The Z, OV, AC and C flags generally reflect the status of the latest operations.

In addition, on entering an interrupt sequence or executing a subroutine call, the status register will not be automatically pushed onto the stack. If the contents of status are important and if the subroutine can corrupt the status register, precaution must be taken to save it properly.

Bit No.	Label	Function
0	С	C is set if an operation results in a carry during an addition operation or if a borrow does not take place during a subtraction operation; otherwise C is cleared. C is also affected by a rotate through carry instruction.
1	AC	AC is set if an operation results in a carry out of the low nibbles in addition or if no borrow from the high nibble into the low nibble in subtraction; otherwise AC is cleared.
2	Z	Z is set if the result of an arithmetic or logical operation is zero; otherwise Z is cleared.
3	OV	OV is set if an operation results in a carry into the highest-order bit but not a carry out of the highest-order bit, or vice versa; otherwise OV is cleared.
4	PDF	PDF is cleared when either a system power-up or executing the CLR WDT instruction. PDF is set by executing a HALT instruction.
5	то	TO is cleared by a system power-up or executing the CLR WDT or HALT instruction. TO is set by a WDT time-out.
6, 7		Unused bit, read as "0"

#### Status (0AH) Register

#### Interrupt

The HT82K68E provides an internal timer counter interrupt and an external interrupt shared with PC2. The interrupt control register (INTC;0BH) contains the interrupt control bits to set not only the enable/disable status but also the interrupt request flags.

Once an interrupt subroutine is serviced, all other interrupts will be blocked (by clearing the EMI bit). This scheme may prevent any further interrupt nesting. Other interrupt requests may occur during this interval but only the interrupt request flag is recorded. If a certain interrupt requires servicing within the service routine, the EMI bit and the corresponding bit of the INTC may be set to allow interrupt nesting. If the stack is full, the interrupt request will not be acknowledged, even if the related interrupt is enabled, until the SP is decremented. If immediate service is desired, the stack must be prevented from becoming full.

All these kinds of interrupt have the wake-up capability. As an interrupt is serviced, a control transfer occurs by pushing the program counter onto the stack followed by a branch to a subroutine at the specified location in the program memory. Only the program counter is pushed onto the stack. If the contents of the register and Status register (STATUS) are altered by the interrupt service program which corrupt the desired control sequence, the contents should be saved in advance.

The internal timer counter interrupt is initialized by setting the timer counter interrupt request flag (T0F; bit 5 of INTC), which is normally caused by a timer counter overflow. When the interrupt is enabled, and the stack is not full and the T0F bit is set, a subroutine call to location 08H will occur. The related interrupt request flag (T0F) will be reset and the EMI bit cleared to disable further interrupts.

The external interrupt is shared with PC2. The external interrupt is activated, the related interrupt request flag (EIF; bit4 of INTC) is then set. When the interrupt is enabled, the stack is not full, and the external interrupt is active, a subroutine call to location 04H will occur. The interrupt request flag (EIF) and EMI bits will also be cleared to disable other interrupts.

The external interrupt (PC2) can be triggered by a high to low transition, or a low to high transition of the PC2, which is dependent on the output level of the PE0. When PE0 is output high, the external interrupt is triggered by a low to high transition of the PC2. When PE0 is output low, the external interrupt is triggered by a high to low transition of PC2.

Bit No.	Label	Function
0	EMI	Controls the master (global) interrupt (1= enabled; 0= disabled)
1	EEI	Control the external interrupt
2	ET0I	Controls the timer counter interrupt (1= enabled; 0= disabled)
3		Unused bit, read as "0"
4	EIF	External interrupt flag
5	T0F	Internal timer counter request flag (1= active; 0= inactive)
6, 7		Unused bit, read as "0"

#### INTC (0BH) Register

During the execution of an interrupt subroutine, other interrupt acknowledgements are held until the RETI instruction is executed or the EMI bit and the related interrupt control bit are set to 1 (if the stack is not full). To return from the interrupt subroutine, a RET or RETI instruction may be invoked. RETI will set the EMI bit to enable an interrupt service, but RET will not.

Interrupts occurring in the interval between the rising edges of two consecutive T2 pulses, will be serviced on the latter of the two T2 pulses, if the corresponding interrupts are enabled. In the case of simultaneous requests, the following table shows the priority that is applied. These can be masked by resetting the EMI bit.

Interrupt Source	Vector
External interrupt 1	04H
Timer counter overflow	08H

The timer counter interrupt request flag (T0F), external interrupt request (EIF) enable timer counter bit (ET0I), enable external interrupt bit (EEI) and enable master interrupt bit (EMI) constitute an interrupt control register (INTC) which is located at 0BH in the data memory. EMI, ET0I and EEI, are used to control the enabling/disabling of interrupts. These bits prevent the requested interrupt from being serviced. Once the interrupt request flags (T0F) are set, they will remain in the INTC register until the interrupts are serviced or cleared by a software instruction.

It is suggested that a program does not use the "CALL subroutine" within the interrupt subroutine. Because interrupts often occur in an unpredictable manner or need to be serviced immediately in some applications, if only one stack is left and enabling the interrupt is not well controlled, once the "CALL subroutine" operates in the interrupt subroutine it will damage the original control sequence.

#### **Oscillator Configuration**

There are two oscillator circuits in HT82K68E. Both are designed for system clocks; the RC oscillator and the Crystal oscillator, which are determined by mask options. No matter what oscillator type is selected, the signal provides the system clock. The HALT mode stops the system oscillator and resists the external signal to conserve power.

System Oscillator

If an RC oscillator is used, an external resistor between OSC1 and VDD is needed and the resistance must range from  $20k\Omega$  to  $47k\Omega$ . The system clock, divided by 4, is available on OSC2, which can be used to synchronize external logic. The RC oscillator provides the most cost effective solution. However, the frequency of the oscillation may vary with VDD, temperature and the chip itself due to process variations. It is, therefore, not suitable for timing sensitive operations where accurate oscillator frequency is desired.

If the Crystal oscillator is used, a crystal across OSC1 and OSC2 is needed to provide the feedback and phase shift needed for oscillator, no other external components are needed. Instead of a crystal, the resonator can also be connected between OSC1 and OSC2 to get a frequency reference, but two external capacitors in OSC1 and OSC2 are required.

The WDT oscillator is a free running on-chip RC oscillator, and no external components are required. Even if the system enters the power down mode, the system clock is stopped, but the WDT oscillator still works for a period of approximately 78 $\mu$ s. The WDT oscillator can be disabled by mask option to conserve power.

#### Watchdog Timer – WDT

The WDT clock source is implemented by a dedicated RC oscillator (WDT oscillator) or instruction clock (system clock divided by 4), decided by mask options. This timer is designed to prevent a software malfunction or sequence jumping to an unknown location with unpredictable results. The Watchdog Timer can be disabled by mask option. If the Watchdog Timer is disabled, all the executions related to the WDT results in no operation.

Once the internal WDT oscillator (RC oscillator normally with a period of  $78\mu s$ ) is selected, it is first divided by 256

Watchdog Timer

(8-stages) to get the nominal time-out period of approximately 20ms. This time-out period may vary with temperature, VDD and process variations. By invoking the WDT prescaler, longer time-out periods can be realized. Writing data to WS2, WS1, WS0 (bit 2,1,0 of the WDTS) can give different time-out periods. If WS2, WS1, WS0 are all equal to 1, the division ratio is up to 1:128, and the maximum time-out period is 2.6 seconds.

If the WDT oscillator is disabled, the WDT clock may still come from the instruction clock and operate in the same manner except that in the HALT state the WDT may stop counting and lose its protecting purpose. In this situation the WDT logic can be restarted by external logic. The high nibble and bit 3 of the WDTS are reserved for user defined flags, which can be used to indicate some specified status.

If the device operates in a noisy environment, using the on-chip RC oscillator (WDT OSC) is strongly recommended, since the HALT will stop the system clock.

WS2	WS1	WS0	Division Ratio
0	0	0	1:1
0	0	1	1:2
0	1	0	1:4
0	1	1	1:8
1	0	0	1:16
1	0	1	1:32
1	1	0	1:64
1	1	1	1:128

#### WDTS (09H) Register

The WDT overflow under normal operation will initialize "chip reset" and set the status bit TO. An overflow in the HALT mode, initializes a "warm reset" only when the program counter and stack pointer are reset to zero. To clear the contents of the WDT (including the WDT prescaler ), three methods are adopted; external reset (a low level to RESET), software instruction(s), or a HALT instruction. There are two types of software instructions; CLR WDT and CLR WDT1/CLR WDT2. Of these two types of instruction, only one can be active depending on the mask option - "CLR WDT times selection option". If the "CLR WDT" is selected (ie. CLR WDT times equal one), any execution of the CLR WDT instruction will clear the WDT. In case "CLR WDT1" and "CLR WDT2" are chosen (ie. CLRWDT times equal two), these two instructions must be executed to clear the WDT; otherwise, the WDT may reset the chip because of the time-out.

#### **Power Down Operation – HALT**

The HALT mode is initialized by the HALT instruction and results in the following...

 The system oscillator will turn off but the WDT oscillator keeps running (if the WDT oscillator is selected).

- The contents of the on Chip RAM and registers remain unchanged.
- WDT and WDT prescaler will be cleared and recount again (if the WDT clock has come from the WDT oscillator).
- All I/O ports maintain their original status.
- The PDF flag is set and the TO flag is cleared.

The system can leave the HALT mode by means of an external reset, interrupt, and external falling edge signal on port A and port C [0:3] or a WDT overflow. An external reset causes a device initialization and the WDT overflow performs a "warm reset". Examining the TO and PDF flags, the reason for chip reset can be determined. The PDF flag is cleared when system power-up or executing the CLR WDT instruction and is set when the HALT instruction is executed. The TO flag is set if the WDT time-out occurs, and causes a wake-up that only resets the program counter and stack pointer, the others keep their original status.

On the other hand, awakening from an external interrupt (PC2), two sequences may happen. If the interrupt is disabled or the interrupt is enabled but the stack is full, the program will resume execution at the next instruction. But if the interrupt is enabled and the stack is not full, the regular interrupt response takes place.

The port A or port C [0:3] wake-up can be considered as a continuation of normal execution. Each bit in port A can be independently selected to wake up the device by mask option. Awakening from an I/O port stimulus, the program will resume execution of the next instruction.

Once a wake-up event occurs, and the system clock comes from a crystal, it takes  $1024 t_{SYS}$  (system clock period) to resume normal operation. In other words, the HT82K68E will insert a dummy period after the wake-up. If the system clock comes from an RC oscillator, it continues operating immediately. If the wake-up results in next instruction execution, this will execute immediately after the dummy period is completed.

To minimize power consumption, all I/O pins should be carefully managed before entering the HALT status.

#### Reset

There are three ways in which a reset can occur:

- RESET reset during normal operation
- RESET reset during HALT
- WDT time-out reset during normal operation

The WDT time-out during HALT is different from other chip reset conditions, since it can perform a warm reset that just resets the program counter and stack pointer, leaving the other circuits to remain in their original state. Some registers remain unchanged during other reset conditions. Most registers are reset to the "initial condition" when the reset conditions are met. By examining the PDF and TO flags, the program can distinguish between different "chip resets".

ſ	то	PDF	RESET Conditions
	0	0	RESET reset during power-up
	u	u	RESET reset during normal operation
	0	1	RESET wake-up HALT
	1	u	WDT time-out during normal operation
	1	1	WDT wake-up HALT

Note: "u" means unchanged

To guarantee that the system oscillator has started and stabilized, the SST (System Start-up Timer) provides an extra-delay of 1024 system clock pulses when the system powers up or when it awakes from the HALT state.

When a system power-up occurs, the SST delay is added during the reset period. But when the reset comes from the  $\overrightarrow{\text{RESET}}$  pin, the SST delay is disabled. Any wake-up from HALT will enable the SST delay.

The functional	unit chip	reset status	is showr	below.
rito fariotional	anne onnp	1000t ottatao	10 0110 111	

Program Counter	000H
Prescaler	Clear
WDT	Clear. After master reset, WDT begins counting
Timer counter	Off
Input/output ports	Input mode
Stack Pointer	Points to the top of the stack

#### **Timer Counter**

A timer counter (TMR) is implemented in the HT82K68E. The timer counter contains an 8-bit programmable count-up counter and the clock may come from the system clock divided by 4.

Using the internal instruction clock, there is only one reference time-base.

There are two registers related to the timer counter; TMR ([0DH]), TMRC ([0EH]). Two physical registers are mapped to TMR location; writing TMR makes the starting value be placed in the timer counter preload register and reading TMR gets the contents of the timer counter. The TMRC is a timer counter control register, which defines some options.

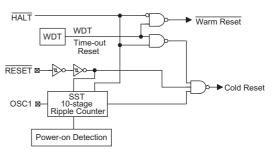

In the timer mode, once the timer counter starts counting, it will count from the current contents in the timer

**Reset Timing Chart** 

Reset Circuit

#### **Reset Configuration**

counter to FFH. Once overflow occurs, the counter is reloaded from the timer counter preload register and generates the interrupt request flag (TF; bit 5 of INTC) at the same time.

To enable the counting operation, the timer ON bit (TON; bit 4 of TMRC) should be set to 1. In the case of timer counter OFF condition, writing data to the timer counter preload register will also reload that data to the timer counter. But if the timer counter is turned on, data written to it will only be kept in the timer counter preload register. The timer counter will still operate until overflow occurs. When the timer counter (reading TMR) is read, the clock will be blocked to avoid errors. As clock blocking may results in a counting error, this must be taken into consideration by the programmer.

Bit No.	Label	Function
0~3		Unused bit, read as "0"
4	TON	To enable/disable timer counting (0= disabled; 1= enabled)
5		Unused bit, read as "0"
6 7	TM0 TM1	10= Timer mode (internal clock)

The state of the registers is summarized in the following table:

Note: "\*" stands for warm reset

"u" stands for unchanged

"x" stands for unknown

**Timer Counter** 

#### Input/Output Ports

There are 32 bidirectional input/output lines in the HT82K68E, labeled from PA to PE, which are mapped to the data memory of [12H], [14H], [16H], [18H] and [1AH] respectively. All these I/O ports can be used for input and output operations. For input operation, these ports are non-latching, that is, the inputs must be ready at the T2 rising edge of instruction MOV A,[m] (m=12H, 14H, 16H, 18H or 1AH). For output operation, all data is latched and remains unchanged until the output latch is rewritten.

Each I/O line has its own control register (PAC, PBC, PCC, PDC, PEC) to control the input/output configuration. With this control register, CMOS output or Schmitt trigger input with or without pull-high resistor (mask option) structures can be reconfigured dynamically (i.e., on-the-fly) under software control. To function as an input, the corresponding latch of the control register must write "1". The pull-high resistance will exhibit automatically if the pull-high option is selected. The input source(s) also depend(s) on the control register. If the control register bit is "1", input will read the pad state. If the control register bit is "0", the contents of the latches will move to the internal bus. The latter is possible in "read-modify-write" instruction. For output function, CMOS is the only configuration. These control registers are mapped to locations 13H, 15H, 17H, 19H and 1BH.

After a chip reset, these input/output lines stay at high levels or floating (mask option). Each bit of these input/output latches can be set or cleared by the SET [m].i or CLR [m].i (m=12H, 14H, 16H, 18H or 1AH) instruction.

Some instructions first input data and then follow the output operations. For example, the SET [m].i, CLR [m].i, CPL [m] and CPLA [m] instructions read the entire port states into the CPU, execute the defined operations (bit-operation), and then write the results back to the latches or the accumulator.

Each line of port A and port C [0:3] has the capability to wake-up the device.

PC2 is shared with the external interrupt pin, PE2~PE4 is defined as CMOS output pins only. PE0 can determine whether the high to low transition, or the low to high transition of PC2 to activate the external subroutine, when PE0 output high, the low to high transition of PC2 to trigger the external subroutine, when PE0 output low, the high to low transition of PC2 to trigger the external subroutine.

PE2~PE4 is configured as CMOS output only and is used to drive the LED. PC0, PC1 is configured as NMOS open drain output with 4.6k $\Omega$  pull-high resistor such that it can easy to use as DATA or CLOCK line of PS2 keyboard application.

#### Low Voltage Reset – LVR

The microcontroller provides low voltage reset circuit in order to monitor the supply voltage of the device. If the supply voltage of the device is within the range  $0.9V \sim V_{LVR}$  such as changing a battery, the LVR will automatically reset the device internally.

The LVR includes the following specifications:

• The low voltage  $(0.9V \sim V_{LVR})$  has to remain in their original state to exceed 1ms. If the low voltage state does not exceed 1ms, the LVR will ignore it and do not perform a reset function.

- The LVR uses the "OR" function with the external  $\overline{\text{RES}}$  signal to perform chip reset.

The relationship between  $V_{\text{DD}}$  and  $V_{\text{LVR}}$  is shown below.

The relationship between  $V_{\text{DD}}$  and  $V_{\text{LVR}}$  is shown below.

Note: V<sub>OPR</sub> is the voltage range for proper chip operation at 4MHz system clock.

- Note: \*1: To make sure that the system oscillator has stabilized, the SST provides an extra delay of 1024 system clock pulses before entering the normal operation.
  - \*2: Since low voltage has to be maintained in its original state and exceed 1ms, therefore 1ms delay enters the reset mode.

### **ROM Code Option**

The following shows six kinds of ROM code option in the HT82K68E. All the ROM code options must be defined to ensure proper system function.

No.	ROM Code Option
1	OSC type selection. This option is to decide if an RC or Crystal oscillator is chosen as system clock. If the Crystal oscillator is selected, the XST (Crystal Start-up Timer) default is activated, otherwise the XST is disabled.
2	WDT source selection. There are three types of selection: on-chip RC oscillator, instruction clock or disable the WDT.
3	CLRWDT times selection. This option defines the way to clear the WDT by instruction. "One time" means that the CLR WDT instruction can clear the WDT. "Two times" means only if both of the CLR WDT1 and CLR WDT2 instructions have been executed, only then will the WDT be cleared.
4	Wake-up selection. This option defines the wake-up function activity. External I/O pins (PA and PC [0:3] only) all have the capability to wake-up the chip from a HALT.
5	Pull-high selection. This option is to decide whether the pull-high resistance is visible or not in the input mode of the I/O ports. Each bit of an I/O port can be independently selected.
6	LVR enable/disable. User can configure whether enable or disable the circuit by configuration option.

DAA [m]	Decimal-	Adjust accu	umulator fo	or addition					
Description	Decimal-Adjust accumulator for addition The accumulator value is adjusted to the BCD (Binary Coded Decimal) code. The accum lator is divided into two nibbles. Each nibble is adjusted to the BCD code and an intern carry (AC1) will be done if the low nibble of the accumulator is greater than 9. The BCD a justment is done by adding 6 to the original value if the original value is greater than 9 or carry (AC or C) is set; otherwise the original value remains unchanged. The result is store in the data memory and only the carry flag (C) may be affected.

## Product Tape and Reel Specifications

### **Reel Dimensions**

### SOP 20W

Symbol	Description	Dimensions in mm
А	Reel Outer Diameter	330±1.0
В	Reel Inner Diameter	62±1.5
с	Spindle Hole Diameter	13.0+0.5 _0.2
D	Key Slit Width	2.0±0.5
T1	Space Between Flange	24.8+0.3 0.2
T2	Reel Thickness	30.2±0.2

### SOP 28W (300mil)

Symbol	Description	Dimensions in mm
А	Reel Outer Diameter	330±1.0
В	Reel Inner Diameter	62±1.5
С	Spindle Hole Diameter	13.0+0.5 0.2
D	Key Slit Width	2.0±0.5
T1	Space Between Flange	24.8+0.3 0.2
T2	Reel Thickness	30.2±0.2

SSOP 48W

Symbol	Description	Dimensions in mm
А	Reel Outer Diameter	330±1.0
В	Reel Inner Diameter	100±0.1
С	Spindle Hole Diameter	13.0+0.5 0.2
D	Key Slit Width	2.0±0.5
T1	Space Between Flange	32.2+0.3 0.2
T2	Reel Thickness	38.2±0.2

### **Carrier Tape Dimensions**

### SOP 20W

Symbol	Description	Dimensions in mm
W	Carrier Tape Width	24.0+0.3 _0.1
Р	Cavity Pitch	12.0±0.1
E	Perforation Position	1.75±0.1
F	Cavity to Perforation (Width Direction)	11.5±0.1
D	Perforation Diameter	1.5+0.1
D1	Cavity Hole Diameter	1.5+0.25
P0	Perforation Pitch	4.0±0.1
P1	Cavity to Perforation (Length Direction)	2.0±0.1
A0	Cavity Length	10.8±0.1
B0	Cavity Width	13.3±0.1
K0	Cavity Depth	3.2±0.1
t	Carrier Tape Thickness	0.3±0.05
С	Cover Tape Width	21.3

### SOP 28W (300mil)

Symbol	Description	Dimensions in mm
W	Carrier Tape Width	24.0±0.3
Р	Cavity Pitch	12.0±0.1
E	Perforation Position	1.75±0.1
F	Cavity to Perforation (Width Direction)	11.5±0.1
D	Perforation Diameter	1.5+0.1
D1	Cavity Hole Diameter	1.5+0.25
P0	Perforation Pitch	4.0±0.1
P1	Cavity to Perforation (Length Direction)	2.0±0.1
A0	Cavity Length	10.85±0.1
B0	Cavity Width	18.34±0.1
K0	Cavity Depth	2.97±0.1
t	Carrier Tape Thickness	0.35±0.01
С	Cover Tape Width	21.3

### SSOP 48W

Symbol	Description	Dimensions in mm
W	Carrier Tape Width	32.0±0.3
Р	Cavity Pitch	16.0±0.1
E	Perforation Position	1.75±0.1
F	Cavity to Perforation (Width Direction)	14.2±0.1
D	Perforation Diameter	2.0 Min.
D1	Cavity Hole Diameter	1.5+0.25
P0	Perforation Pitch	4.0±0.1
P1	Cavity to Perforation (Length Direction)	2.0±0.1
A0	Cavity Length	12.0±0.1
B0	Cavity Width	16.20±0.1
K1	Cavity Depth	2.4±0.1
K2	Cavity Depth	3.2±0.1
t	Carrier Tape Thickness	0.35±0.05
С	Cover Tape Width	25.5
