

## FEATURES

- **Wide Operating Voltage Range: 2.9V to 26.5V**
- **Adjustable, 5% Accurate (15mV) Current Limit**
- Current Monitor Output
- Adjustable Current Limit Timer Before Fault
- Powergood and Fault Outputs
- Adjustable Inrush Current Control
- 2% Accurate Undervoltage and Overvoltage Protection
- Available in 16-Lead SSOP and 16-Pin 5mm × 3mm DFN Packages

## APPLICATIONS

- RAID Systems
- ATCA, AMC,  $\mu$ TCA Systems
- Server I/O Cards
- Industrial

## DESCRIPTION

The LTC<sup>®</sup>4218 is a Hot Swap<sup>™</sup> controller that allows a board to be safely inserted and removed from a live backplane. An internal high side switch driver controls the gate of an external N-channel MOSFET for supply voltages from 2.9V to 26.5V. A dedicated 12V version (LTC4218-12) contains preset 12V specific thresholds, while the standard LTC4218 allows adjustable thresholds.

The LTC4218 provides an accurate (5%) current limit with current foldback limiting. The current limit threshold can be adjusted dynamically using an external pin. Additional features include a current monitor output that amplifies the sense voltage for ground referenced current sensing. Overvoltage, undervoltage and powergood monitoring are also provided.

LT, LT, LTC and LTM are registered trademarks of Linear Technology Corporation. Hot Swap is a trademark of Linear Technology Corporation. All other trademarks are the property of their respective owners.

## TYPICAL APPLICATION

12V, 6A Card Resident Application

Power-Up Waveform

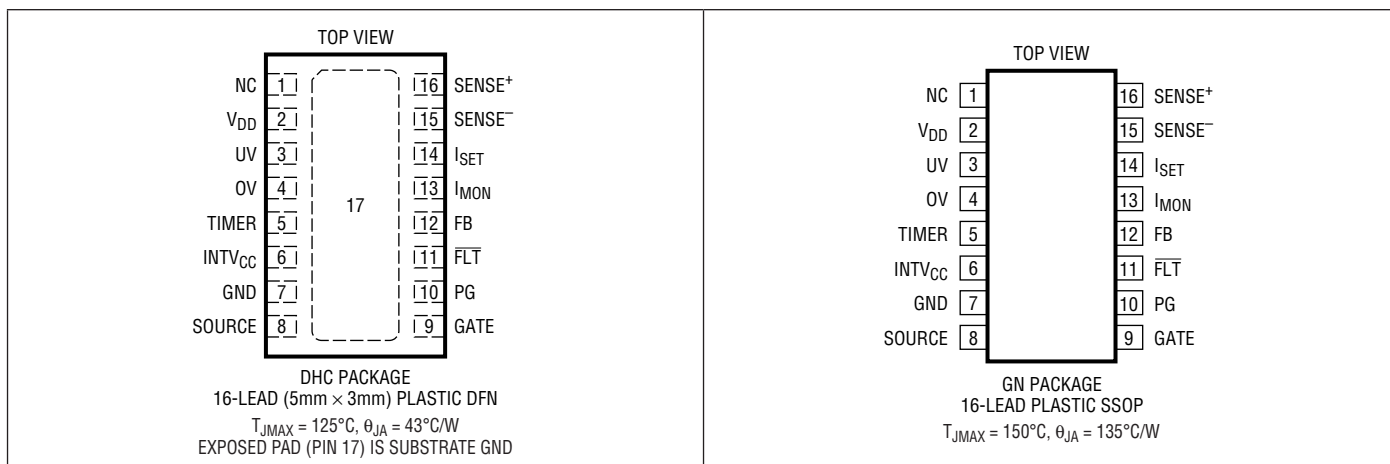

# LTC4218

## ABSOLUTE MAXIMUM RATINGS

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** All currents into pins are positive, all voltages are referenced to GND unless otherwise specified.

**Note 3:** An internal clamp limits the GATE pin to a maximum of 6.5V above the SOURCE pin. Driving either GATE or SOURCE pin to voltages beyond the clamp may damage the device.

## PIN FUNCTIONS

**Exposed Pad:** Exposed pad may be left open or connected to device ground.

**FB:** Foldback and Power Good Comparator Input. Connect this pin to an external resistive divider from SOURCE for the LTC4218 (adjustable version). The LTC4218-12 version uses a fixed internal divider with optional external adjustment. Open the pin if the LTC4218-12 thresholds for 12V operation are desired. If the voltage falls below 0.6V, the output power is considered bad and the current limit is reduced. If the voltage falls below 1.21V the PG pin will pull low to indicate the power is bad.

**$\overline{\text{FLT}}$ :** Overcurrent Fault Indicator. Open drain output pulls low when an overcurrent fault has occurred and the circuit breaker trips. For overcurrent auto-retry tie to UV pin (see Applications Information for details).

**GATE:** Gate Drive for External N-Channel FET. An internal 24 $\mu$ A current source charges the gate of the external N-channel MOSFET. A resistor and capacitor network from this pin to ground sets the turn-on rate. During an undervoltage or overvoltage generated turn-off a 250 $\mu$ A pull-down current turns the MOSFET off. During a short circuit or undervoltage lockout, a 170mA pull-down current source between GATE and SOURCE is activated.

**GND:** Device Ground.

**$I_{\text{MON}}$ :** Current Monitor Output. The current sourced from this pin is defined as the current sense voltage (between the SENSE<sup>+</sup> and SENSE<sup>-</sup> pins) multiplied by 6.67 $\mu$ A/mV. Placing a 20k resistor from this pin to GND creates a 0V to 2V voltage swing when the current sense voltage ranges from 0mV to 15mV.

**INTV<sub>CC</sub>:** Internal 3V Supply Decoupling Output. This pin must have a 0.1 $\mu$ F or larger capacitor.

**$I_{\text{SET}}$ :** Current Limit Adjustment Pin. For 15mV current limit threshold, open this pin. This pin is driven by a 20k resistor in series with a voltage source. The pin voltage is used to generate the current limit threshold. The internal 20k resistor and an external resistor between  $I_{\text{SET}}$  and ground create an attenuator that lowers the current limit value.

**NC:** No Connection

**OV:** Overvoltage Comparator Input. Connect this pin to an external resistive divider from V<sub>DD</sub> for the LTC4218 (adjustable version). The LTC4218-12 version uses a fixed internal divider with optional external adjustment for 12V operation. Open the pin if the LTC4218-12 thresholds are desired. If the voltage at this pin rises above 1.235V, an overvoltage is detected and the switch turns off. Tie to GND if unused.

**PG:** Power Good Indicator. Open drain output pulls low when the FB pin drops below 1.21V indicating the power is bad.

**SENSE<sup>-</sup>:** Current Sense Minus Input. Connect this pin to the opposite of V<sub>DD</sub> current sense resistor side. The current limit circuit controls the GATE pin to limit the sense voltage between the SENSE<sup>+</sup> and SENSE<sup>-</sup> pins to 15mV or less depending on the voltage at the FB pin.

**SENSE<sup>+</sup>:** Current Sense Plus Input. Connect this pin to the V<sub>DD</sub> side of the current sense resistor.

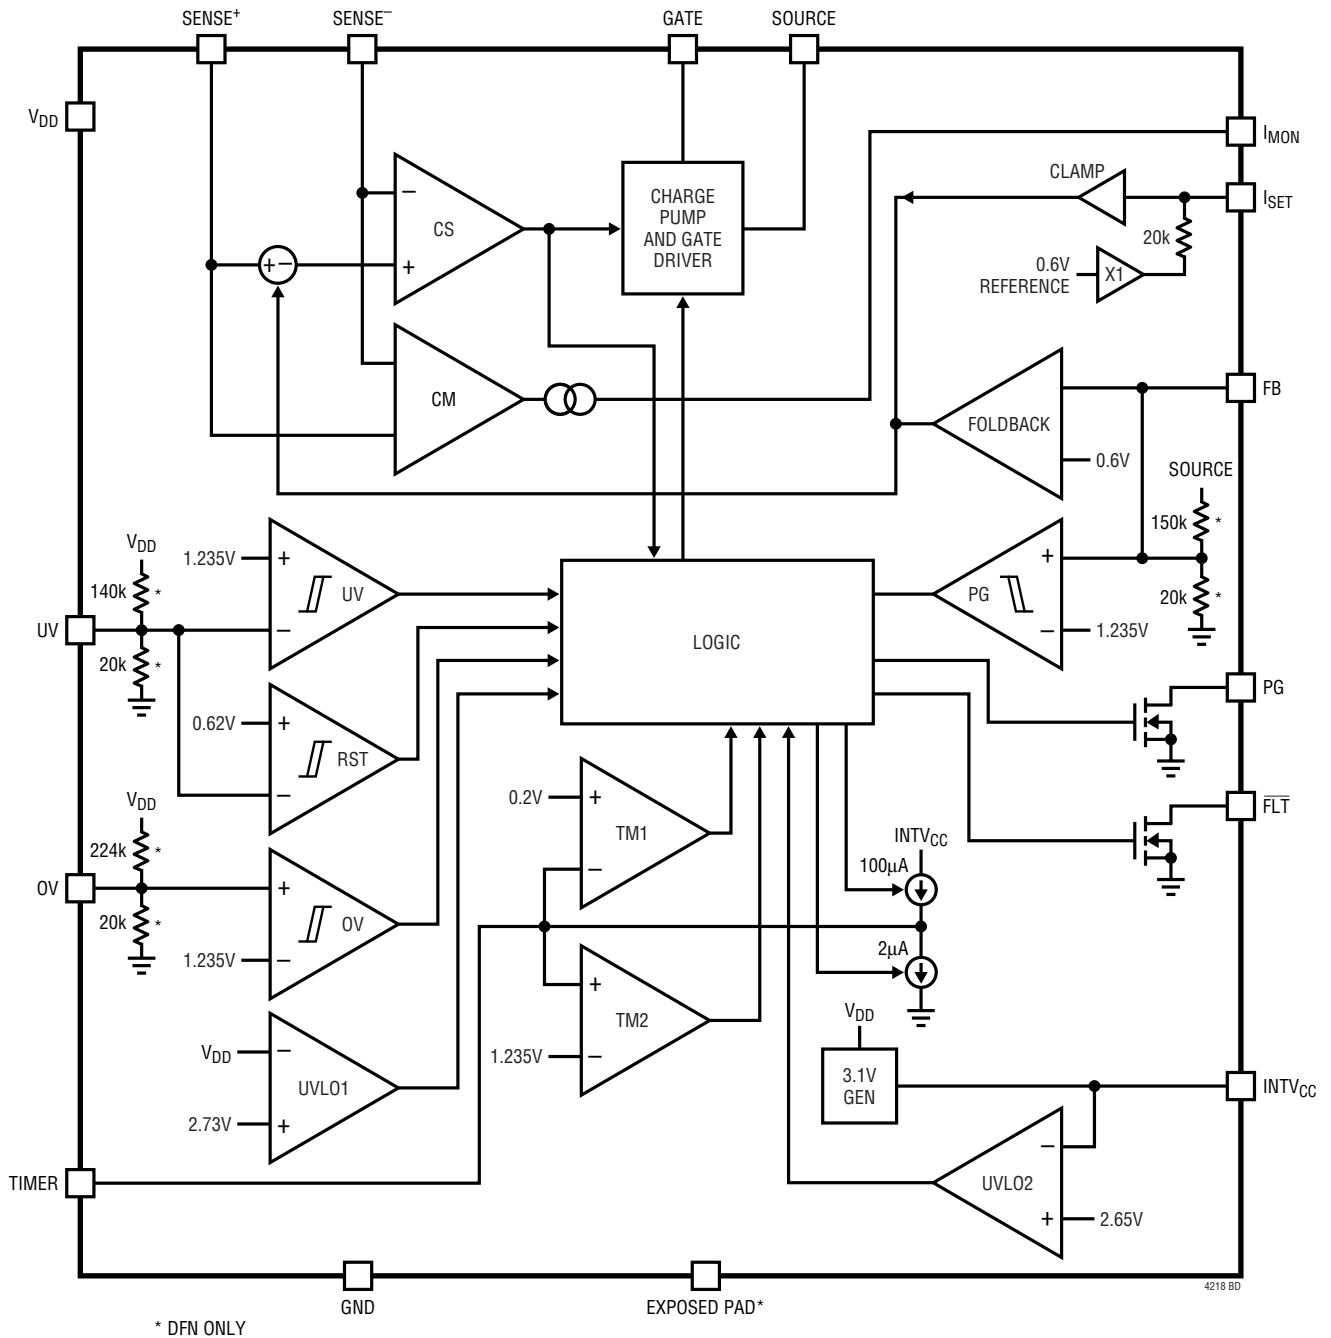

**SOURCE:** N-Channel MOSFET Source Connection. Connect this pin to the source of the external N-channel MOSFET switch. This pin provides a return for the gate pull-down circuit. In the LTC4218-12 version, the powergood comparator monitors an internal resistive divider between the SOURCE pin and GND.

**TIMER:** Timer Input. Connect a capacitor between this pin and ground to set a 12ms/ $\mu$ F duration for current limit before the switch is turned off. If the UV pin is toggled low while the MOSFET switch is off, the switch will turn on again following a cool down time of 518ms/ $\mu$ F duration.

**UV:** Undervoltage Comparator Input. Tie high if unused. Connect this pin to an external resistive divider from V<sub>DD</sub> for the LTC4218 (adjustable version). The LTC4218-12 version drives the UV pin with an internal resistive divider from V<sub>DD</sub>. Open the pin if the preset LTC4218-12 thresholds for 12V operation are desired. If the UV pin voltage falls below 1.15V, an undervoltage is detected and the switch turns off. Pulling this pin below 0.62V resets the overcurrent fault and allows the switch to turn back on (see Applications Information for details). If overcurrent auto-retry is desired then tie this pin to the  $\overline{\text{FLT}}$  pin.

**V<sub>DD</sub>:** Supply Voltage. This pin has an undervoltage lockout threshold of 2.73V.

## FUNCTIONAL DIAGRAM

## OPERATION

The Functional Diagram displays the main circuits of the device. The LTC4218 is designed to turn a board's supply voltage on and off in a controlled manner, allowing the board to be safely inserted and removed from a live backplane. During normal operation, the charge pump and gate driver turn on the external N-channel pass FET's gate to provide power to the load.

The current sense (CS) amplifier monitors the load current using the voltage sensed across the current sense resistor. The CS amplifier limits the current in the load by reducing the GATE-to-SOURCE voltage in an active control loop. It is simple to adjust the current limit threshold using the current setting ( $I_{SET}$ ) pin. This allows a different threshold during other times such as startup.

A short circuit on the output to ground causes significant power dissipation during active current limiting. To limit this power, the foldback amplifier reduces the current limit value from 15mV to 3.75mV (referred to the SENSE<sup>+</sup> minus SENSE<sup>-</sup> voltage) in a linear manner as the FB pin drops below 0.6V (see Typical Performance Characteristics).

If an overcurrent condition persists, the TIMER pin ramps up with a 100 $\mu$ A current source until the pin voltage exceeds 1.2V (comparator TM2). This indicates to the logic that it is time to turn off the MOSFET to prevent overheating. At this point the TIMER pin ramps down using the 2 $\mu$ A current source until the voltage drops below 0.2V (Comparator TM1) which tells the logic to start an internal 100ms timer.

At this point, the pass transistor has cooled and it is safe to turn it on again.

The fixed 12V version, LTC4218-12, uses two separate internal dividers from  $V_{DD}$  to drive the UV and OV pins. This version also features a divider from the SOURCE pin to drive the FB pin. The LTC4218-12 is available in a DFN package while the LTC4218 (adjustable version) is in a SSOP package.

The output voltage is monitored using the FB pin and the PG comparator to determine if the power is available for the load. The power good condition is signaled by the PG pin using an open-drain pull-down transistor.

The Functional Diagram shows the monitoring blocks of the LTC4218. The comparators on the left side include the UV and OV comparators. These comparators are used to determine if the external conditions are valid prior to turning on the MOSFET. But first, the undervoltage lockout circuits (UVLO1 and UVLO2) must validate the input supply and internally generated 3.1V supply ( $INTV_{CC}$ ) and generate the power up initialization to the logic circuits. If the external conditions remain valid for 100ms the MOSFET is allowed to turn on.

Other monitoring features include the  $I_{MON}$  current monitor. The current monitor (CM) outputs a current proportional to the sense resistor current. This current can drive an external resistor or other circuits for monitoring purposes.

## APPLICATIONS INFORMATION

The typical LTC4218 application is in a high availability system that uses a positive voltage supply to distribute power to individual cards. The basic application circuit is shown in Figure 1. External component selection is discussed in detail in the following sections.

Figure 1. 3A, 12V Card Resident Application

### Turn-On Sequence

The power supply on a board is controlled by placing an external N-channel pass transistor (Q1) in the power path. Note the sense resistor ( $R_S$ ) detects current and the capacitor ( $C_{GATE}$ ) controls gate slew rate. Resistor R1 prevents high frequency oscillations in Q1 and resistor  $R_{GATE}$  isolates  $C_{GATE}$  during fast turn-off.

Several conditions must be present before the external pass transistor can be turned on. First, the supply  $V_{DD}$  must exceed its undervoltage lockout level. Next, the internally generated supply  $INTV_{CC}$  must cross its 2.65V undervoltage threshold. This generates a 25µs power-on-reset pulse which clears the logic's fault register and initializes internal latches.

After the power-on-reset pulse, the LTC4218 will go through the following sequence. First, the UV and OV pins must indicate that the input power is within the acceptable range. All of these conditions must be satisfied for a duration of 100ms to ensure that any contact bounce during the insertion has ended.

The pass transistor is turned on by charging up the GATE with a 24µA charge pump generated current source (Figure 2).

Figure 2. Supply Turn-On

The voltage at the GATE pin rises with a slope equal to  $24\mu A/C_{GATE}$  and the supply inrush current is set at:

$$I_{INRUSH} = \frac{C_L}{C_{GATE}} \cdot 24\mu A$$

When the GATE voltage reaches the MOSFET threshold voltage, the switch begins to turn on and the SOURCE voltage follows the GATE voltage as it increases. Once SOURCE reaches  $V_{DD}$ , the GATE will ramp up until clamped by the 6.15V zener between GATE and SOURCE.

As the SOURCE pin voltage rises, so will the FB pin which is monitoring it. If the voltage across the current sense resistor ( $R_S$ ) gets too high, the inrush current will be limited by the internal current limiting circuitry. Once the FB pin crosses its 1.235V threshold and the GATE to SOURCE voltage exceeds 4.2V, the PG pin will cease to pull low and indicate that the power is good.

### Turn-Off Sequence

The switch can be turned off by a variety of conditions. A normal turn-off is initiated by the UV pin going below its 1.235V threshold. Additionally, several fault conditions will turn off the switch. These include an input overvoltage (OV pin) and overcurrent circuit breaker (SENSE pin). Normally, the switch is turned off with a 250µA current pulling down the GATE pin to ground. With the switch turned off, the SOURCE pin voltage drops which pulls the FB pin below

## APPLICATIONS INFORMATION

its threshold. The PG then pulls low to indicate output power is no longer good.

If  $V_{DD}$  drops below 2.65V for greater than 5 $\mu$ s or  $INTV_{CC}$  drops below 2.5V for greater than 1 $\mu$ s, a fast shutdown of the switch is initiated. The GATE is pulled down with a 170mA current to the SOURCE pin.

### Overcurrent Fault

The LTC4218 features an adjustable current limit with foldback that protects the MOSFET when excessive load current happens. To protect the switch during active current limit, the available current is reduced as a function of the output voltage sensed by the FB pin. A graph in the Typical Performance Characteristics shows the current limit versus FB voltage.

An overcurrent fault occurs when the current limit circuitry has been engaged for longer than the time-out delay set by the TIMER. Current limiting begins when the current sense voltage between the SENSE<sup>+</sup> and SENSE<sup>-</sup> pins reaches 3.75mV to 15mV (depending on the foldback). The GATE pin is then brought down with a 170mA GATE-to-SOURCE current. The voltage on the GATE is regulated in order to limit the current sense voltage to less than 15mV. At this point, a circuit breaker time delay starts by charging the external timing capacitor from the TIMER pin with a 100 $\mu$ A pull-up current. If the TIMER pin reaches its 1.2V threshold, the external switch turns off (with a 250 $\mu$ A current from GATE to ground). Next, the  $\overline{FLT}$  pin is pulled low to indicate an overcurrent fault has turned off the MOSFET. For a given the circuit breaker time delay, the equation for setting the timing capacitor's value is as follows:

$$C_T = T_{CB} \cdot 0.083[\mu\text{F}/\text{ms}]$$

After the switch is turned off, the TIMER pin begins discharging the timing capacitor with a 2 $\mu$ A pull-down current. When the TIMER pin reaches its 0.2V threshold, the switch is allowed to turn on again if the overcurrent fault has been cleared. Bringing the UV pin below 0.6V and then high will clear the fault. If the TIMER pin is tied to  $INTV_{CC}$ , then the switch is allowed to turn on again (after an internal 100ms delay) if the overcurrent fault is cleared.

Tying the  $\overline{FLT}$  pin to the UV pin allows the part to self-clear the fault and turn the MOSFET on as soon as TIMER pin has ramped below 0.2V. In this auto retry mode, the LTC4218 repeatedly tries to turn on after an overcurrent at a period determined by the capacitor on the TIMER pin.

The waveform in Figure 3 shows how the output latches off following a short circuit. The drop across the sense resistor is 3.75mV as the timer ramps up.

Figure 3. Short-Circuit Waveform

### Current Limit Adjustment

The default value of the active current limiting signal threshold is 15mV. The current limit threshold can be adjusted lower by placing a resistor on the  $I_{SET}$  pin. As shown in the Functional Diagram the voltage at the  $I_{SET}$  pin (via the clamp circuit) sets the CS amplifier's built-in offset voltage. This offset voltage directly determines the active current limit value. With the  $I_{SET}$  pin open, the voltage at the  $I_{SET}$  pin is determined by the buffered reference voltage. This voltage is set to 0.618V which corresponds to a 15mV current limit threshold.

An external resistor placed between the  $I_{SET}$  pin and ground forms a resistive divider with the internal 20k sourcing resistor. The divider acts to lower the voltage at the  $I_{SET}$  pin and therefore lower the current limit threshold. The overall current limit threshold precision is reduced to  $\pm 11\%$  when using a 20k resistor to half the threshold.

## APPLICATIONS INFORMATION

Using a switch (connected to ground) in series with the external resistor allows the active current limit to change only when the switch is closed. This feature can be used when the startup current exceeds the typical maximum load current.

### Monitor MOSFET Current

The current in the MOSFET passes through the sense resistor. The voltage on the sense resistor is converted to a current that is sourced out of the  $I_{MON}$  pin. The gain of the  $I_{SENSE}$  amplifier is  $100\mu A$  from  $I_{MON}$  for  $15mV$  on the sense resistor. This output current can be converted to a voltage using an external resistor to drive a comparator or ADC. The voltage compliance for the  $I_{MON}$  pin is from  $0V$  to  $INTV_{CC} - 0.7V$ .

A microcontroller with a built-in comparator can build a simple integrating single-slope ADC by resetting a capacitor that is charged with this current. When the capacitor voltage trips the comparator and the capacitor is reset, a timer is started. The time between resets will indicate the MOSFET current.

### Monitor OV and UV Faults

Protecting the load from an overvoltage condition is the main function of the OV pin. In the LTC4218-12 an internal resistive divider (driving the OV pin) connects to a comparator to turn off the MOSFET when the  $V_{DD}$  voltage exceeds  $15.05V$ . If the  $V_{DD}$  pin subsequently falls back below  $14.8V$ , the switch will be allowed to turn on immediately. In the LTC4218, the OV pin threshold is  $1.23V$  when rising and  $1.21V$  when falling out of overvoltage.

The UV pin functions as an undervoltage protection pin or as an “on” pin. In the LTC4218-12 the MOSFET turns off when  $V_{DD}$  falls below  $9.23V$ . If the  $V_{DD}$  pin subsequently rises above  $9.88V$  for  $100ms$ , the switch will be allowed to turn on again. The LTC4218 UV turn on/off threshold is  $1.23V$  (rising) and  $1.15V$  (falling).

In the case of an undervoltage or overvoltage, the MOSFET turns off and there is indication on the PG status pin. When the overvoltage is removed, the MOSFET’s gate ramps up immediately.

### Powergood Indication

In addition to setting the foldback current limit threshold, the FB pin is used to determine a powergood condition. The LTC4218-12 uses an internal resistive divider on the SOURCE pin to drive the FB pin. The PG comparator indicates logic high when SOURCE pin rises above  $10.5V$ . If the SOURCE pin subsequently falls below  $10.3V$ , the comparator toggles low. On the LTC4218 the PG comparator drives high when the FB pin rises above  $1.23V$  and low when falls below  $1.21V$ .

Once the PG comparator is high, the GATE pin voltage is monitored with respect to the SOURCE pin. Once the GATE minus SOURCE voltage exceeds  $4.2V$ , the PG pin goes high. This indicates to the system that it is safe to load the Output while the MOSFET is completely turned “on”. The PG pin goes low when the GATE is commanded off (using the UV, OV or SENSE+/SENSE- pins) or when the PG comparator drives low.

### 12V Fixed Version

In the LTC4218-12, the UV, OV and FB pins are driven by internal dividers which may need to be filtered to prevent false faults. By placing a bypass capacitor on these pins the faults are delayed by the RC time constant. Use the  $R_{IN}$  value from the electrical table for this calculation.

In cases where the fixed thresholds need a slight adjustment, placing a resistor from the UV or OV pins to  $V_{DD}$  or GND will adjust the threshold up or down. Likewise, placing a resistor between FB pin to OUT or GND adjusts the threshold. Again, use the  $R_{IN}$  value from the electrical table for this calculation.

An example in Figure 4 raises the UV turn-on voltage from  $9.88V$  to  $10.5V$ . Increasing the UV level requires adding a resistor between UV and ground. The resistor, ( $R_{SHUNT1}$ ), can be calculated using electrical table parameters as follows:

$$R_{SHUNT1} = \frac{R_{(IN)} \cdot V_{OLD}}{(V_{NEW} - V_{OLD})} = \frac{18k \cdot 9.88}{(10.5 - 9.88)} = 287k$$

## APPLICATIONS INFORMATION

Figure 4. Adjusting LTC4218-12 Thresholds

In this same figure the OV threshold is lowered from 15.05V to 13.5V. Decreasing the OV threshold requires adding a resistor between  $V_{DD}$  and OV. This resistor can be calculated as follows:

$$R_{SHUNT2} = \frac{R_{(IN)} \cdot V_{OLD}}{V_{(TH)}} \left( \frac{(V_{NEW} - V_{OV(TH)})}{(V_{OLD} - V_{NEW})} \right) =$$

$$\frac{18k \cdot 15.05}{1.235} \left( \frac{(13.5 - 1.235)}{(15.05 - 13.5)} \right) = 1.736M$$

Use the equation for  $R_{SHUNT1}$  for increasing the OV and FB thresholds. Likewise, use the equation for  $R_{SHUNT2}$  for decreasing the UV and FB thresholds.

## Design Example

Consider the following design example (Figure 5):  $V_{IN} = 12V$ ,  $I_{MAX} = 7.5A$ ,  $I_{INRUSH} = 1A$ ,  $C_L = 330\mu F$ ,  $V_{UVON} = 9.88V$ ,  $V_{OV(OFF)} = 15.05V$ ,  $V_{PWRGD} = 10.5V$ . A current limit fault triggers an automatic restart of the power up sequence.

The selection of the sense resistor, ( $R_S$ ), is set by the overcurrent threshold of 15mV:

$$R_S = 15mV / I_{MAX} = 15mV / 7.5A = 0.002\Omega$$

The MOSFET should be sized to handle the power dissipation during the inrush charging of the output capacitor  $C_{OUT}$ . The method used to determine the power in Q1 is the principal:

$$E_C = \text{Energy in } C_L = \text{Energy in } Q1$$

Thus:

$$E_C = \frac{1}{2} CV^2 = \frac{1}{2} (330\mu F)(12)^2 = 0.048J$$

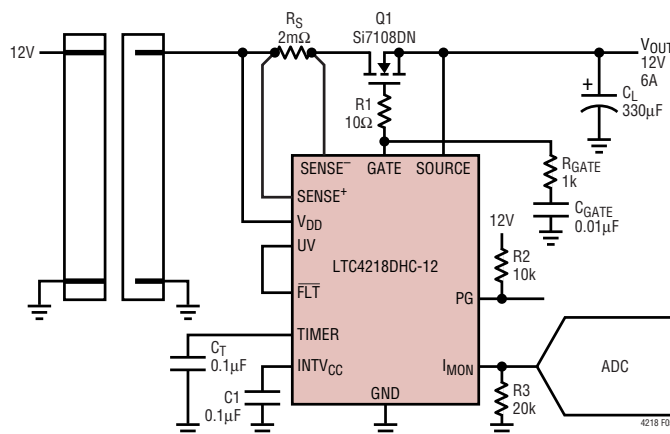

Figure 5. 6A, 12V Card Resident Application

Calculate the time it takes to charge up  $C_{OUT}$ :

$$t_{CHARGUP} = \frac{C_L \cdot V_{IN}}{I_{INRUSH}} = \frac{330\mu F \cdot 12V}{1A} = 4ms$$

The inrush current is set to 1A using  $C_{GATE}$ :

$$C_{GATE} = C_L \frac{I_{GATE(UP)}}{I_{INRUSH}} = 330\mu F \frac{24\mu A}{1A} \cong 0.01\mu F$$

The average power dissipated in the MOSFET:

$$P_{DISS} = E_C / t_{CHARGUP} = 0.048J / 4ms = 12W$$

The SOA (safe operating area) curves of candidate MOSFETs must be evaluated to ensure that the heat capacity of the package can stand 12W for 4ms. The SOA curves of the Vishay Siliconix Si7108DN provide 1.5A at 10V (15W) for 100ms, satisfying the requirement.

Next, the power dissipated in the MOSFET during overcurrent must be limited. The active current limit uses a timer to prevent excessive energy dissipation in the MOSFET. The worst-case power occurs when the voltage versus current profile of the foldback current limit is at the maximum. This occurs when the current is 6A and the voltage is one half of 12V or (6V). See the Current Limit Sense Voltage vs FB Voltage in the Typical Performance curves to view this profile. In order to survive 36W, the MOSFET SOA dictates a maximum time at this power level. The Si7108DN allows 60W for 10ms or less. Therefore, it is acceptable to set the current limit timeout using  $C_T$  to be 1.2ms:

$$C_T = 1.2ms / 12[ms/\mu F] = 0.1\mu F$$

## APPLICATIONS INFORMATION

After the 1.2ms timeout the  $\overline{\text{FLT}}$  pin needs to pull down on the UV pin to restart the power-up sequence.

Since the default values for overvoltage, undervoltage and powergood thresholds for the 12V fixed version match the requirements, no external components are required for the UV, OV and FB pins.

The final schematic results in very few external components. Resistor R1 ( $10\Omega$ ) prevents high frequency oscillations in Q1 while  $R_{\text{GATE}}$  of 1k isolates  $C_{\text{GATE}}$  during fast turn-off. The pull-up resistor, (R2), connects to the PG pin while the 20k (R3) converts the  $I_{\text{MON}}$  current to a voltage at a ratio:

$$V_{I_{\text{MON}}} = \frac{6.67\mu\text{A}}{\text{mV}} \cdot \frac{2\text{mV}}{\text{A}} \cdot 20\text{k} = \frac{0.267\text{V}}{\text{A}}$$

In addition, there is a  $0.1\mu\text{F}$  bypass (C1) on the  $\text{INTV}_{\text{CC}}$  pin.

### Layout Considerations

To achieve accurate current sensing, a Kelvin connection for the sense resistor is recommended. The PCB layout should be balanced and symmetrical to minimize wiring errors. In addition, the PCB layout for the sense resistors and the power MOSFETs should include good thermal management techniques for optimal device power dissipation. A recommended PCB layout for the sense resistor and power MOSFET is illustrated in Figure 6.

Figure 6. Recommended Layout

In Hot Swap applications where load currents can be 6A, narrow PCB tracks exhibit more resistances than wider tracks and operate at elevated temperatures. The minimum trace width for 1oz copper foil is 0.02" per amp to make sure the trace stays at a reasonable temperature. Using 0.03" per amp or wider is recommended. Note that 1oz copper exhibits a sheet resistance of about  $0.5\text{m}\Omega/\text{square}$ . Small resistances add up quickly in high current applications

It is also important to put C1, the bypass capacitor for the  $\text{INTV}_{\text{CC}}$  pin, as close as possible between the  $\text{INTV}_{\text{CC}}$  and GND. Place the  $10\Omega$  resistor as close as possible to Q1. This will limit the parasitic trace capacitance that leads to Q1 self-oscillation.

### Additional Applications

The LTC4218 has a wide operating range from 2.9V to 26.5V. The UV, OV and PG thresholds are set with a few resistors. All other functions are independent of supply voltage.

The last page includes a 24V application with a UV threshold of 19.8V, an OV threshold of 28.3V and a PG threshold of 20.75V. Figure 7 shows a 3.3V application with a UV threshold of 2.87V, an OV threshold of 3.77V and a PG threshold of 3.05V.
