

MITSUBISHI ICs (TV)  
**M52026SP**

**SECAM CHROMA SIGNAL PROCESSOR**

**DESCRIPTION**

The M52026SP is a semiconductor integrated circuit for processing color signals for SECAM color television sets. This IC consists of a limiter amplifier, color signal demodulator, IDENT detector, SECAM switch, system discriminator, system switch, color saturation control, matrix, AM modulator, local oscillator and DC regenerating circuit.

**FEATURES**

- Reduced crosstalk
- Small number of external components
- Superior linearity of color signal detector
- Few PAL/SECAM system switching errors
- Wide range of operating supply voltage

**APPLICATION**

SECAM system color TV

**PIN CONFIGURATION (TOP VIEW)**

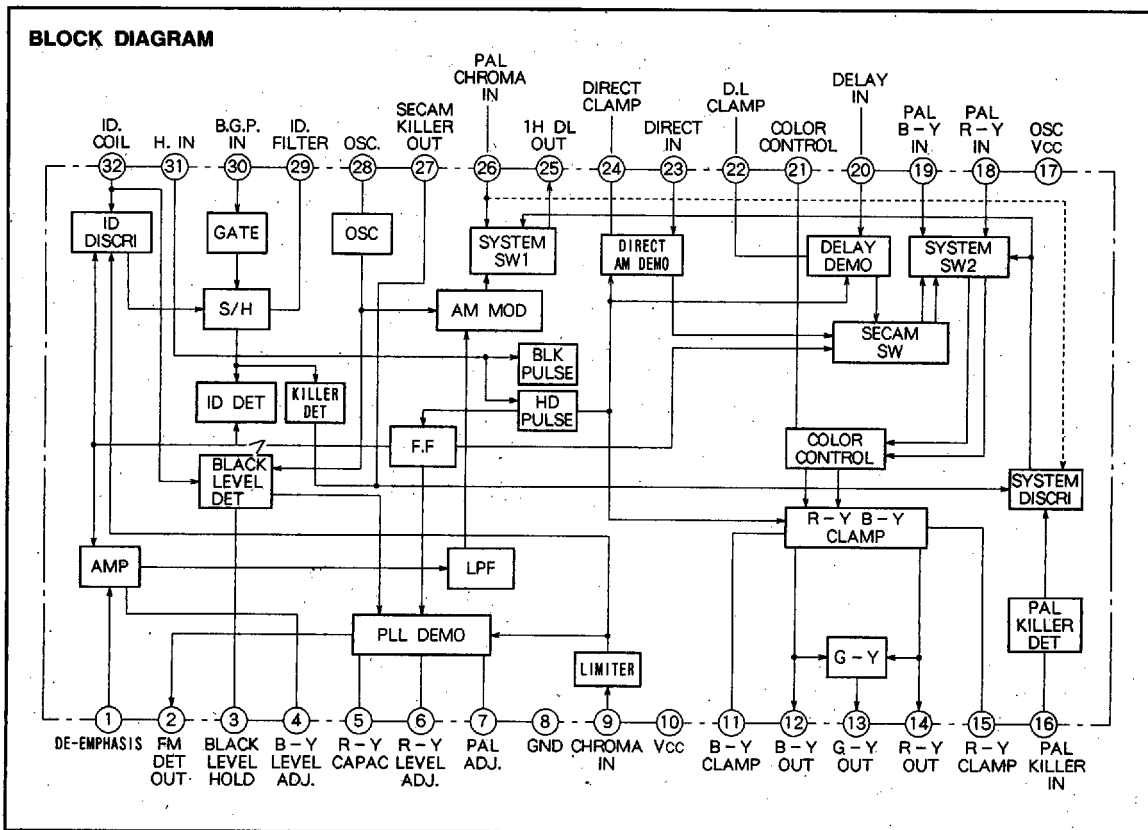

Outline 32P4B

**RECOMMENDED OPERATING CONDITION**

Supply Voltage Range ..... 8.5~13V

Rated Supply Voltage ..... 11V

**BLOCK DIAGRAM**

# M52026SP

## SECAM CHROMA SIGNAL PROCESSOR

**Note12.** Measure 4.25MHz leaking to pin ⑤ and assume it to be  $X_{VP-P}$ .  $CT_{1s}$  is determined by:

$$CT_{1s} = 20 \log \frac{z}{x}$$

**Note13.** Observe pin ⑤ and increase VEXT2 from 0V, then measure the VEXT2 voltage when 4.25MHz is absent.

**Note14.**  $M_{AM} = \frac{f}{e} \times 100\%$

**Note15.** Set VEXT3 to 5.7V. Change VEXT1 so that the average voltage on pin ⑫ becomes 7.2V. At this time, measure the distortion at pins ⑫, ⑭.

**Note16.** Assume the output level at pins ⑫, ⑭ in Note14 above to be  $X_{VP-P}$ .  $G_{CAM}$  is found by:

$$G_{CAM} = 20 \log \frac{x}{Input} \text{ (dB)}$$

**Note17.** Change VEXT1 so that the average voltage on pin ⑫ becomes 7.2V. At this time, measure the output level.

**Note18.** Set VEXT1 in the same manner as in Note17 above and measure the output level as  $X_{VP-P}$ .

$$CC_1 = 20 \log \frac{x}{V_{O12}} \text{ or } 20 \log \frac{x}{V_{O14}} \text{ (dB)}$$

**Note19.** Measure the output level as  $X_{VP-P}$ .

$$G_{MAX} = 20 \log \frac{x}{0.7} \text{ (dB)}$$

However, set VEXT1 in the same manner as in Note16 above.

**Note20.** Measure the voltage difference between the output clamp period and other periods.

**Note21.** Change SG8 from 100kHz so that the output amplitude at pins ⑫, ⑭ is -3dB from the level of 100kHz.

**Note22.** With the delay of output waveform (direct side) at pin ⑫ for SG4 inputted to C IN as  $T_{DL}$ , measure the condition at rise.

**Note23.** Increase VEXT1 from 4V and define it as  $V_{BGPON}$  when pin ⑯ voltage is 0.6V or less. Decrease it further from  $V_{BGPON}$  and define VEXT1 as  $V_{BGPOFF}$  when it is 0.6V or more.

**Note24.** Increase VEXT1 from 0V, and define it as  $V_{VTH}$  when pin ③ voltage is approx. 3V.

**Note25.** Increase VEXT1 from 0V and define pin ⑮ voltage as  $V_{BLK}$  when the waveform on pin ⑫ disappears.

**Note26.** Decrease VEXT1 from  $V_{CC}$ , and define the maximum voltage on pin ⑮ as  $V_{FF}$  when the waveform on pin ⑫ disappears.

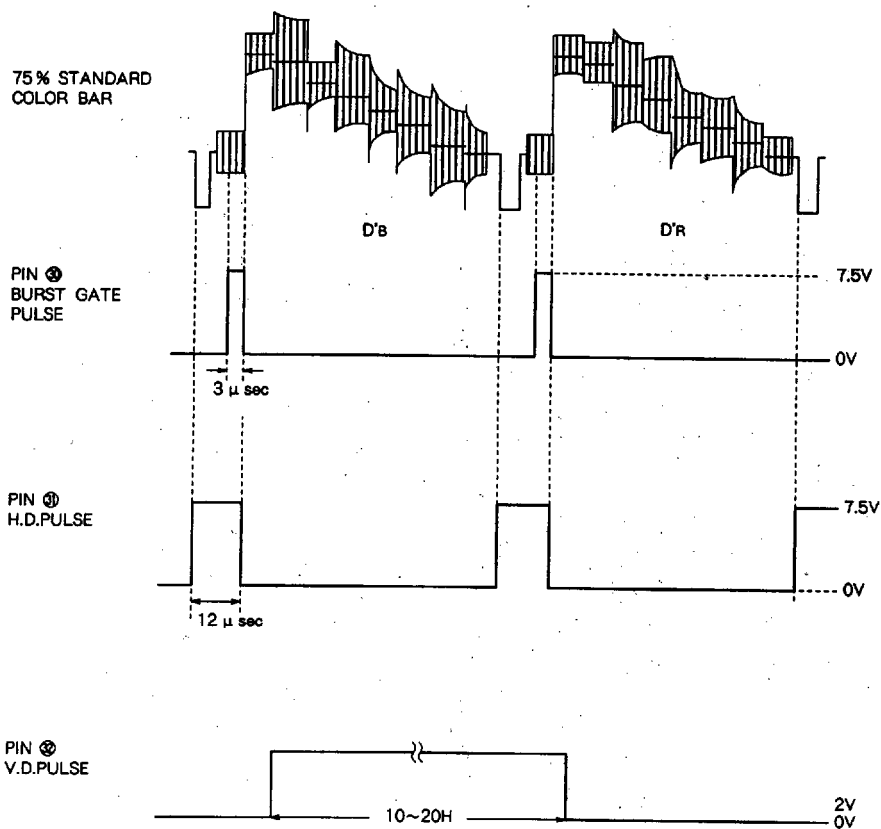

## M52026SP

## SECAM CHROMA SIGNAL PROCESSOR

**Point of Caution In Electrical Characteristic Testing:**

- 1) For this IC to operate normally, it is necessary to input each pulse with timing and pulse width as shown below.  
(when  $V_{CC}=12V$ )

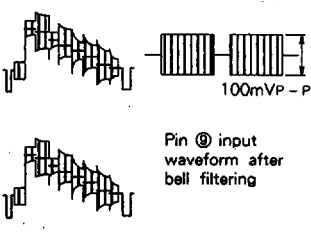

- 2) When SECAM signal is input, adjust the IDENT coil so that IDENT filter pin (pin ④) voltage becomes maximum.  
(when  $V_{CC}=12V$  and  $V_{29}$ =approx.9.6V)

# M52026SP

## SECAM CHROMA SIGNAL PROCESSOR

### INPUT SIGNAL

| SG No. | Signal name             | Signal contents   |
|--------|-------------------------|---|
| SG0    | 75% standard color bar  |  <p>100mV<sub>P-P</sub></p> <p>Pin ⑨ input waveform after bell filtering</p> |
| SG1    | 4.328MHz CW             | 100mV <sub>P-P</sub>  |
| SG2    | Monochrome signal       |   |
| SG3    | $f_0 = 4.25\text{MHz}$  | 75kHz dev FM $f_m = 400\text{Hz}$<br>30% AM $f_m = 400\text{Hz}$  |
| SG4    |                         | Signal in which only R-Y is monochrome from 75% standard color bar signal   |
| SG5    | 4.0MHz CW               |   |
| SG6    | $f_0 = 4.3\text{MHz}$   | 50% AM $f_m = 400\text{Hz}$   |
| SG7    | 500kHz CW               |   |
| SG8    | 100mV <sub>P-P</sub> CW | Frequency variable  |

The loop time constant for the PLL is designed to be sufficiently short in order to respond well to the chroma signal. The VCO control characteristics show good linearity compared with Quadrature type FM demodulators.

It is possible to adjust the freerun frequency of the VCO by varying the resistor at pin 7, as follows: for good linearity adjust the DC output voltage at pin 7, using VR, to the non-signal level of 3V DC when the input to the VCO is at 4.33MHz.

The B-Y black level is determined by the frequency of the local oscillator; therefore, during the vertical blanking period the local oscillator is switched to the input of the PLL FM detector in place of the limiter output; this input is demodulated to the black level voltage. This voltage is then input to the sample and hold circuit. The S/H circuit stores the black level which, during the horizontal blanking period, is switched to the amplifier preceding the carrier filter.

### PRECAUTIONS FOR APPLICATION

#### 1. Colour signal demodulator

The M52026SP uses a phase locked loop (PLL) for FM detection of colour signals.

The chroma signal is input through a bell filter and passed, via pin 9, to the input of a limiter amplifier (DC gain = 64 dB) which limits the signal amplitude. The signal is then input to the PLL detector. The following figure outlines the structure of the FM detector.

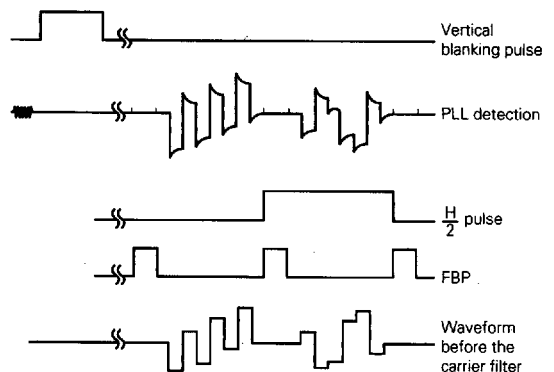

The PLL consists of an emitter coupled multivibrator VCO and double balanced multiplier. The output of the VCO is multiplied by the limiter output, and this is fed back to the VCO. When the PLL is locked on to the input of the FM detector, the output of the PLL becomes the phase detector output, which is passed on to the LPF.

The R-Y black level is adjusted to the B-Y black level by varying the external resistor at pin 6.

Pin 7's external resistor adjusts the VCO free-run frequency; this, however, does not affect the B-Y black level.

# M52026SP

## SECAM CHROMA SIGNAL PROCESSOR

### 2. B-Y & R-Y amps

The signal obtained by the PLL FM demodulator is input the amplifier circuit after de-emphasis by external parts. Then R-Y is phase inverted, and the gain ratio of R-Y and B-Y is

$$\frac{R-Y}{B-Y} = -0.7$$

The colour difference signals are passed alternately (switched by the H/2 pulse) to the H and V blanking circuits.

### 3. Ident Detector

The ident detector uses Quadrature FM detection. During the H/2 pulse, the detection output is reversed every 1H and is sampled during the gate pulse, the value being held for one line period, and then the voltage is output at pin 29.

Ident and killer detection are performed by means of comparison with this DC voltage.

When ident is normal, the voltage at pin 29 rises above that of the non-signal level.

The ident technique employed by the M52026SP is the Line ident system, which requires a line burst gate pulse; but it is possible to add field ident gate pulses without affecting normal operation.

During the V blanking pulse, which is input at pin 32, the B-Y blank-level is sampled and held.

The V blanking pulse is approximately 2V relative to the ground.

### 4. AM modulator and oscillator

The colour difference signal, after passing through the LPF, is amplitude modulated and output from pin 25. The modulation depth is fixed. The local oscillator is connected to the crystal, via pin 28; the other side of the crystal is connected to the ground.

### 5. AM detector, SECAM switch

The following figure shows how the AM modulated signal, output from pin 25, is demodulated to colour difference signals.

Pin 25 outputs the chroma signal, and the direct signal is input to pin 23, the delayed signal to pin 20. After each signal is AM detected, R-Y and B-Y are obtained by switching between detector outputs every 1H.

### 6. System switches

There are two PAL/SECAM switching systems

#### System switch I

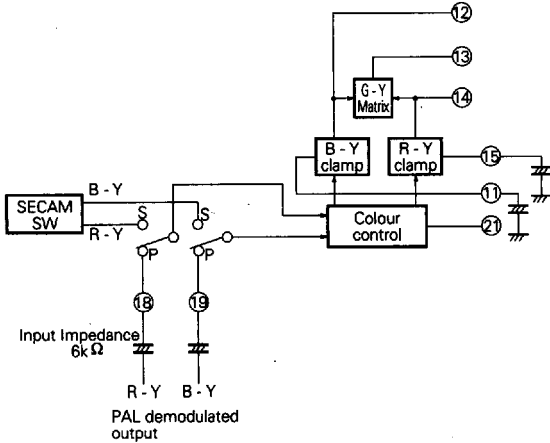

This switch is used to switch input signals of 1HDL

SECAM CHROMA SIGNAL PROCESSOR

**System switch II**

This switch is used to switch between R-Y and B-Y signals.

The R-Y signal and B-Y signal pass through this system switch and are routed to the colour control circuit, where clamping takes place; G-Y is obtained.

**7. System Identification**

This IC can be operated in both SECAM priority mode and PAL priority mode. In both cases, the system is prevented from malfunctioning by the killer output applied to pin 16.

| Input Condition                   | SECAM ID  | PAL ID  | SECAM priority system identification | PAL priority system identification |
|-----------------------------------|-----------|---------|--------------------------------------|------------------------------------|
| Monochrome or weak electric field | NOT SECAM | NOT PAL | PAL                                  | SECAM                              |
| PAL receiving                     | NOT SECAM | PAL     | PAL                                  | PAL                                |
| SECAM receiving                   | SECAM     | NOT PAL | SECAM                                | SECAM                              |
| Misoperation                      | SECAM     | PAL     | Previous system                      | Previous system                    |

Pin 16 is the input of the PAL killer signal from the PAL IC. If this signal is high (threshold voltage is 1.5V), then PAL is present (PAL); if low, then PAL is not present (NOT PAL).

Pin 27 is the output of the SECAM killer signal. If it is high (0.9V), then SECAM is not present (NOT SECAM); if low, then SECAM is present (SECAM).

How SECAM killer signal output is obtained.

**8. H, V pulse**

HD pulse and blanking pulse are input from pin 31.

**9. Burst gate pulse**

Burst gate pulse is input from pin 30.

**Note**

This IC requires a 4.25MHz crystal with a parallel resonance point. The crystal should have good temperature characteristics.

The following figure shows how to adjust the location of the burst gate pulse at pin 29.

The width should be approximately 3μsec. The location and width can be varied by adding external circuitry at pin 30.

**M52026SP**

**SECAM CHROMA SIGNAL PROCESSOR**

BGP in the figure to the left is soldered externally as shown below.
