

MC33690

MC33690 Standalone Tag Reader Circuit

The standalone tag reader circuit (STARC) is an integrated circuit dedicated to the automotive immobilizer applications. It combines the antenna drivers and demodulator necessary to interface with a transponder.

A low dropout voltage regulator and a physical interface fully compatible with the ISO 9141 norm are also available.

The STARC is fabricated with the SMARTMOSTM3.5 technology. This process is a double layer metal 1.4µm 45V technology, combining CMOS and bipolar devices.

- Contactless 125 kHz tag reader module:
 - Self synchronous sample and hold demodulator
 - Amplitude or phase modulation detection
 - High sensitivity
 - Fast read after write demodulator settling time
 - Low resistance and high current antenna drivers, 2W @ 150mA (typ.)
 - Bidirectionnal data transmission
 - Multi-tag, multi-scheme operation
- Low dropout voltage regulator:
 - Wide input supply voltage range from 5.5V up to 40V
 - Output current capability up to 150mA DC with an external power transistor
 - 5V output voltage with a ±5% accuracy
 - Low voltage reset function
 - Low current consumption in standby mode:
 - 300µA (typ.)
- ISO 9141 transmitter and receiver module:
 - Input voltage thresholds ratiometric to the supply voltage
 - Current limitation
 - Output slew rate control
 - No external protection device required

Pin Connections

1 Description

1.1 Tag Reader Module

The tag reader module is dedicated for automotive or industrial applications where information has to be transmitted contactless. The tag reader module is a write/read (challenge/response) controller for applications that demand high security level.

The tag reader module is connected to a serial-tuned LC circuit that generates a magnetic field power supplying the tag. The use of a synchronous sample and hold technique allows communication with all available tags using admittance switching producing absorption of the RF field.

Load amplitude or phase shift modulation can be detected at high bit rates up to 8 kHz. The typical operational carrier frequency of the tag reader module with an 8 MHz clock is 125 kHz.

Figure 2. Tag Reader Block Diagram

2 Read Function

When answering to the base station, a transponder generates an absorption modulation of the magnetic field. It results in an amplitude/phase modulation of the current across the antenna. This information is picked up at the antenna tap point between the coil and the capacitor. An external resistive ladder down scales this voltage to a level compatible with the demodulator input voltage range (see Section 15, “Tag Reader”).

The demodulator (see Figure 2) consists of:

- an input stage (emitter follower)
- a sample and hold circuit
- a voltage follower
- a low offset voltage comparator

The sampling time is automatically set to take into account a phase shift due to the tolerances of the antenna components (L and C) and of the oscillator. The allowed phase shift measured at the input RD ranges from -45° to $+45^\circ$. Assuming that the phase

reference is the falling edge of the driving signal TD1, this leads to a sampling time phase ranging from -78.75° to 90° with discrete steps of 11.25° . After reset condition, the sampling time phase is $+11.25^\circ$.

The antenna phase shift evaluation is only done after each wake-up command or after reset. This is necessary to obtain the best demodulator performances.

To ensure a fast demodulator settling time after wake-up, reset, or a write sequence, the external capacitor CEXT is preloaded at its working voltage. This preset occurs $256\mu\text{s}$ after switching the antenna drivers on and its duration is $128\mu\text{s}$. After wake-up or reset, the preset has the same duration, but begins $518\mu\text{s}$ after clock settling. After power on reset, VSUP must meet the minimum specified value, enabling the nominal operation of VDD, before the start of the preset. Otherwise, the preset must be done through a standby/wake-up sequence.

3 Write Function

Whatever the selected configuration (see Section 6, “Communication Modes Description”), the write function is achieved by switching on/off the output drivers TD1/2. After the drivers have been set in high impedance, the load current flows alternatively through the internal diodes to VSS and to VDD (see Figure 3).

Figure 3. Current Flow When Buffers are Switched Off

4 Voltage Regulator

The low dropout voltage regulator provides a regulated 5V supply for the internal circuitry. It can also supply external peripherals or sensors. The input supply voltage ranges from 5.5V to over 40V.

This voltage regulator uses a series combination of high voltage LDMOS and low voltage PMOS transistors to provide regulation. An external low ESR capacitor is required for the regulator stability.

The maximum average current is limited by the power dissipation capability of the SO 20 package. This limitation can be overcome by connecting an external N channel MOS parallel with the internal LDMOS. The threshold voltage of this transistor must be lower than the one of the internal LDMOS (1.95V typ.) to prevent the current from flowing into the LDMOS. Its breakdown voltage must be higher than the maximum supply voltage.

A low-voltage reset function monitors the VDD output. An internal $10\mu\text{A}$ pull-up current source allows, when an external capacitor is connected between LVR and GND, to generate delays at power up (5ms typ. with $C_{Reset}=22\text{nF}$). The LVR pin is

ISO 9141 Physical Interface

also the input generating the internal reset signal. Applying a logic low level on this pin resets the circuit, all the internal flip flops are reset, and drivers TD1/2 are switched on.

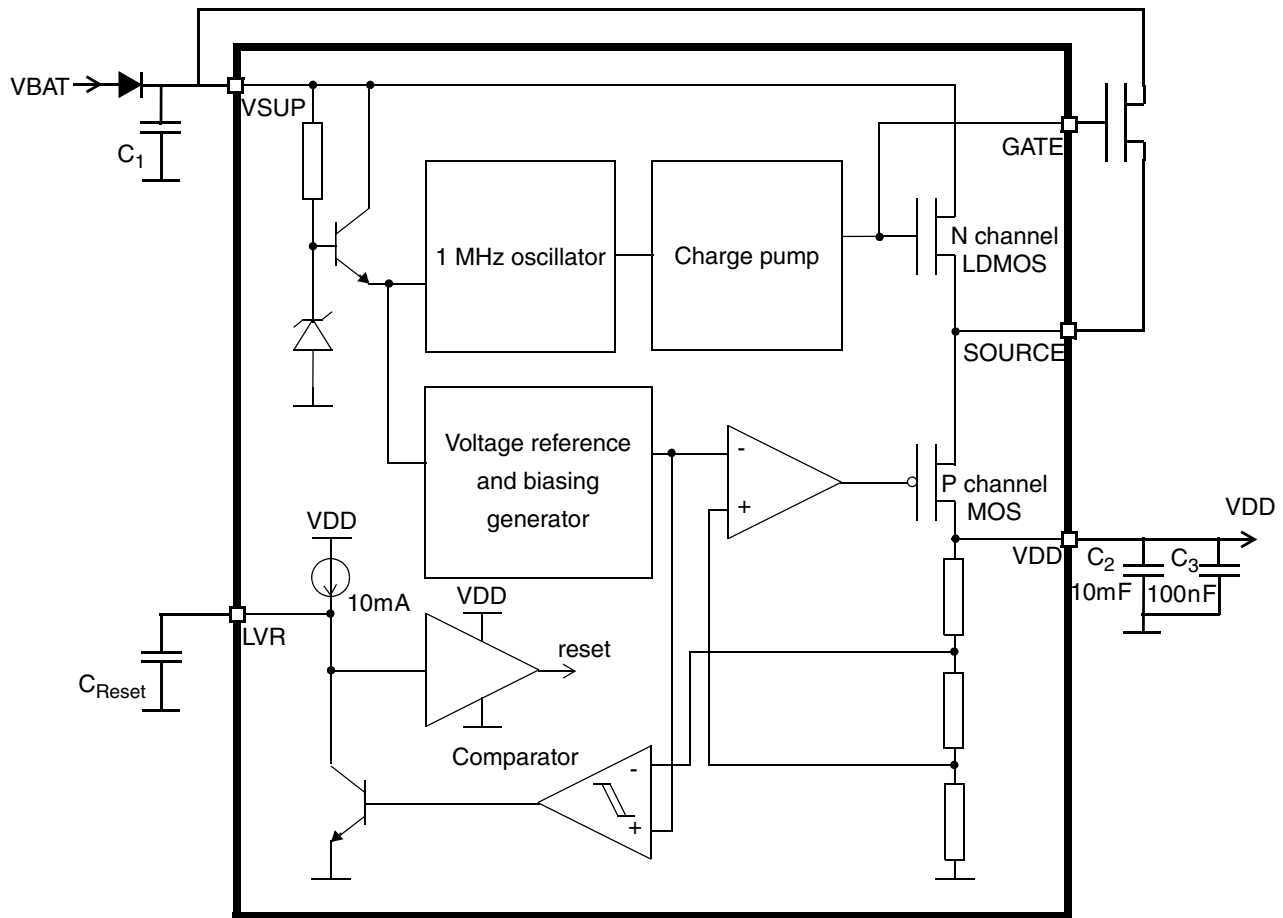

Figure 4. Voltage Regulator Block Diagram

5 ISO 9141 Physical Interface

This interface module is fully compatible with the ISO 9141 norm describing the diagnosis line. It includes one transmitter (pin K) and two receivers (pins K and AM).

The input stages consist of high-voltage CMOS triggers. The thresholds are ratiometric to VSUP. A ground referenced current source (2.5 μ A typ.) pulls down the input when unconnected.

When a negative voltage is applied on the K or AM lines, the input current is internally limited by a 2k Ω resistor (typ.) in series with a diode.

A current limitation allows the transmitter to drive any capacitive load and protects against short circuit to the battery voltage. An overtemperature protection shuts the driver down when the junction temperature exceeds 150°C (typ). After shutdown by the overtemperature protection, the driver can be switched on again if the junction temperature has decreased below the threshold and by applying an off/on command, coming from the demodulator in configurations A and B, or directly applied on the input Tx in configuration C (see [Table 4](#)).

The electromagnetic emission is reduced because of the voltage slew rate control (5V/ μ s typ.).

Figure 5. ISO 9141 Interface

6 Communication Modes Description

The STARC offers three different communication modes. Therefore, it can be used as a standalone circuit connected to an electronic control unit (ECU) through a bus line or it can be directly connected to a microcontroller in case of a single board architecture.

Table 4. Communication Modes Description

Configuration			Configuration Pins		Pin Status Function Description
Type	Bus Type	Name	Mode1	Mode2	
Standalone	1 wire (VBAT)	A	0	0	K output/input: <ul style="list-style-type: none"> • demodulator output • amplitude modulation input • shutdown/wake-up AM must be connected to VSUP DOUT forces a low level

Direct Connection to a MCU	2 wires (VDD)	C	1	x	DOUT output: <ul style="list-style-type: none"> • demodulator output AM input: <ul style="list-style-type: none"> • amplitude modulation input MODE2 input: <ul style="list-style-type: none"> • shutdown/wake-up
				1	K output/input (standalone ISO 9141 interface): <ul style="list-style-type: none"> • driven by Tx and monitored by Rx
				0	K input (standalone ISO 9141 interface): <ul style="list-style-type: none"> • monitored by Rx • Tx disabled

7 Standalone Configuration with One-Wire Bus

When a low level is applied on pins MODE1 and MODE2, the circuit is in configuration A (see [Figure 24](#)). After power on, the circuit is set into read mode. The demodulator output is directly routed to the ISO 9141 interface output K.

The circuit can be set into write mode at anytime by violation of all possible patterns on the single wire bus during more than 1ms. Then, the K line achieves the amplitude modulation by switching on/off both antenna drivers.

After 1ms of inactivity at the end of the challenge phase (bus in idle recessive one state), the circuit is set back into read mode.

The circuit can be put into standby mode by forcing the K line at zero during more than 2 ms after entering the write mode. After the K line is released, the circuit sends an acknowledge pulse before entering into standby mode. In standby mode, the oscillator and most of the internal biasing currents are switched off. Therefore, the functions (tag reader, ISO 9141 driver) are inactive except the voltage regulator and the ISO 9141 receiver on pin K. The driver output TD1 forces a low level and TD2 forces a high level. A rising edge on K wakes up the circuit. After completion of the wake-up sequence, the circuit is automatically set in read mode.

In configuration A, DOUT and Rx outputs always force a low level and Tx is disabled.

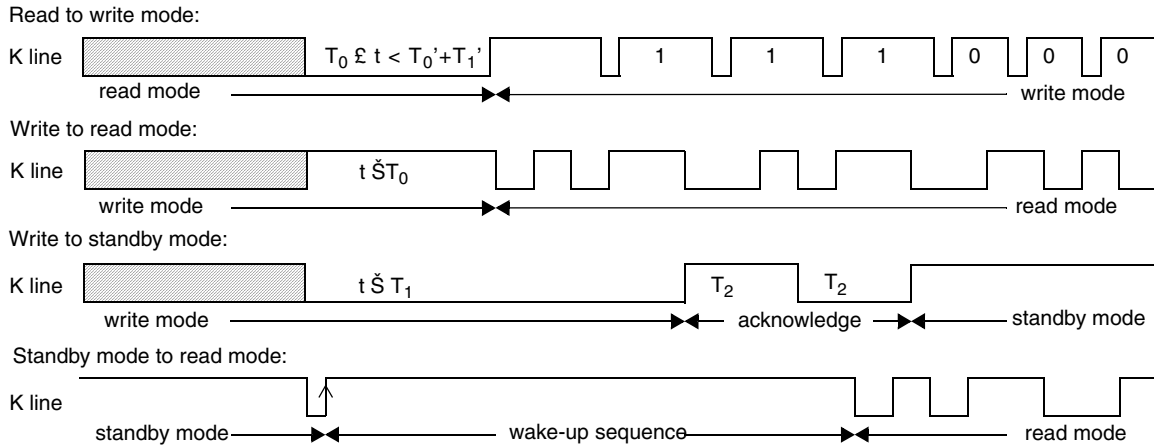

Figure 6. Mode Access Description in One-Wire Bus Configuration

Figure 7. Configuration A State Diagram

7.1 Timing Definitions for a 8 MHz Crystal

The timing definitions for a 8 MHz crystal are:

- T_{ref} is crystal oscillator period (125 ns typ.)
- $T_0=8064.T_{ref} = 1.008ms$ typ.
- $T_0'=7932.T_{ref} = 0.992ms$ typ.
- $T_1=16256.T_{ref} = 2.032ms$ typ.
- $T_1'=16128.T_{ref} = 2.016ms$ typ.
- $T_2=4096.T_{ref} = 512\mu s$ typ.

T_0 is the minimum time required to guarantee the device toggles from read to write (or from write to read). However, the STARC may toggle from read to write (or from write to read) between T_0 and T_0' .

T_1 is the minimum time required to guarantee the device toggles from write to standby. However, the STARC may toggle in standby between T_1 and T_1' .

8 Standalone Configuration with Two-Wire Bus

When a low level is applied on MODE1 and a high level on MODE2, the circuit is in configuration B (see Figure 25). The K pin is set as an output sending the demodulated data.

The AM pin is set as a VSUP referenced input pin receiving the amplitude modulation and the shutdown/wake-up commands. Forcing high and low levels on AM achieves the amplitude modulation by switching on/off both antenna drivers. This amplitude modulation can be monitored on the K output and allows antenna short and open circuit diagnosis. The circuit can be put into standby mode by forcing the AM line at zero during more than 2 ms. The circuit sends an acknowledge pulse before entering into standby mode.

In standby mode, the oscillator and most of the internal biasing currents are switched off. Therefore, the functions (tag reader and ISO 9141 driver) are inactive except for the voltage regulator and the ISO 9141 receiver on pin AM. The driver output TD1 forces a low level and TD2 a high level. A rising edge on AM wakes up the circuit. After completion of the wake-up sequence, the circuit is automatically set in read mode.

In configuration B, DOUT and Rx outputs always force a low level and Tx is disabled.

Figure 8. Modes Access Description in Two-wire Bus Configuration

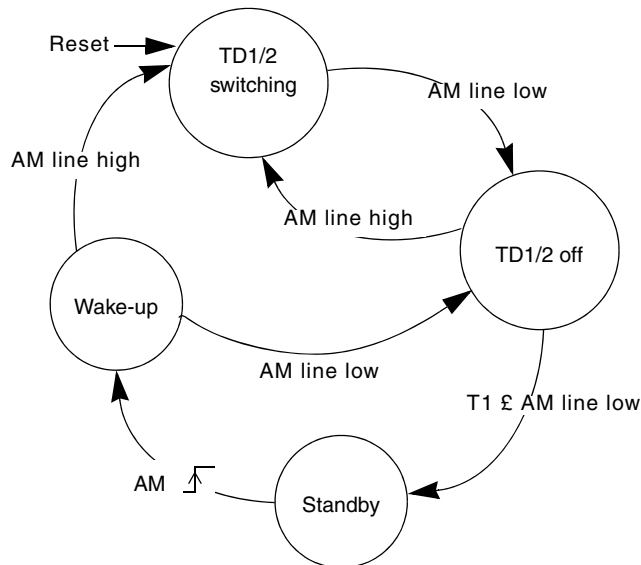

Figure 9. Configuration B State Diagram

9 Direct Connection to a Microcontroller Configuration

When a high level is applied on MODE1, the circuit is in configuration C (see Figure 26). The demodulated data are sent through DOUT.

The AM pin is set as a VDD referenced input pin receiving the AM command. Forcing high and low levels on AM achieves the amplitude modulation by switching on/off both antenna drivers. Meanwhile, this amplitude modulation can be monitored on DOUT. This allows antenna short and open circuit diagnosis.

The circuit can be put into standby mode by applying a low level on the MODE2 pin. In standby mode, the oscillator and most of the internal biasing currents are switched off. Therefore, the functions (tag reader and ISO 9141 interface) are inactive except for the voltage regulator. The driver outputs TD1 and TD2 are frozen in their state (high or low level) before entering into standby mode. DOUT forces a low level.

The ISO 9141 interface K is standalone and can be directly controlled by the input pin Tx and monitored by the output Rx. Applying a logic high level on Tx switches the output driver K on (dominant zero state when an external pull-up resistor is connected between K and VBAT). Applying a logic low level turns the driver off (one recessive state).

Rx monitors the voltage at the K pin. When the voltage is below the low threshold voltage, Rx forces a logic low level. When the voltage is above the high threshold voltage, Rx forces a logic high level.

In standby mode, Tx is disabled and Rx output monitors the voltage at the K pin.

	Characteristic	Symbol	Test Condition and Comments	Min	Typ	Max	Unit	Type
Input (pins MODE1, MODE2, AM, TX)								
6.0	Input Low Voltage	V_{ILD}	—	0	—	$0.3 \times V_{DD}$	V	—
6.1	Input High Voltage	V_{IHD}	—	$0.7 \times V_{DD}$	—	V_{DD}	V	—
6.2	Input Hysteresis Voltage	V_{HD}	—	.24	.7	1	V	—
Output (pins DOUT,RX)								
7.0	Output Low Voltage	V_{OL}	$I_{LOAD} = 500\mu A$	0	0.5	$0.2 \times V_{DD}$	V	—
7.1	Output High Voltage	V_{OH}	$I_{LOAD} = -500\mu A$	$0.8 \times V_{DD}$	4.6	V_{DD}	V	—
7.2	Fall/Rise Time	$t_{F/R}$	$C_{LOAD} = 10pF$, Calculated from 10% to 90% of the output swing	—	—	150	ns	—

18 Pin Definition and Function

The internal circuits connected to the pins of the device are shown in Figures 13 – 23, including the diodes used for ESD protection.

19 Application Schemes

Note: If no external MOS transistor is necessary to increase the voltage regulator current capability, the pins GATE and SOURCE must be left unconnected. In this configuration, the outputs Rx and DOUT force a low level. C1 is not required for the STARC functionality and only acts as a reservoir of energy. To preserve the demodulator sensitivity, CEXT and R2 should be connected to AGND and VSS connected to AGND using a low resistance path.

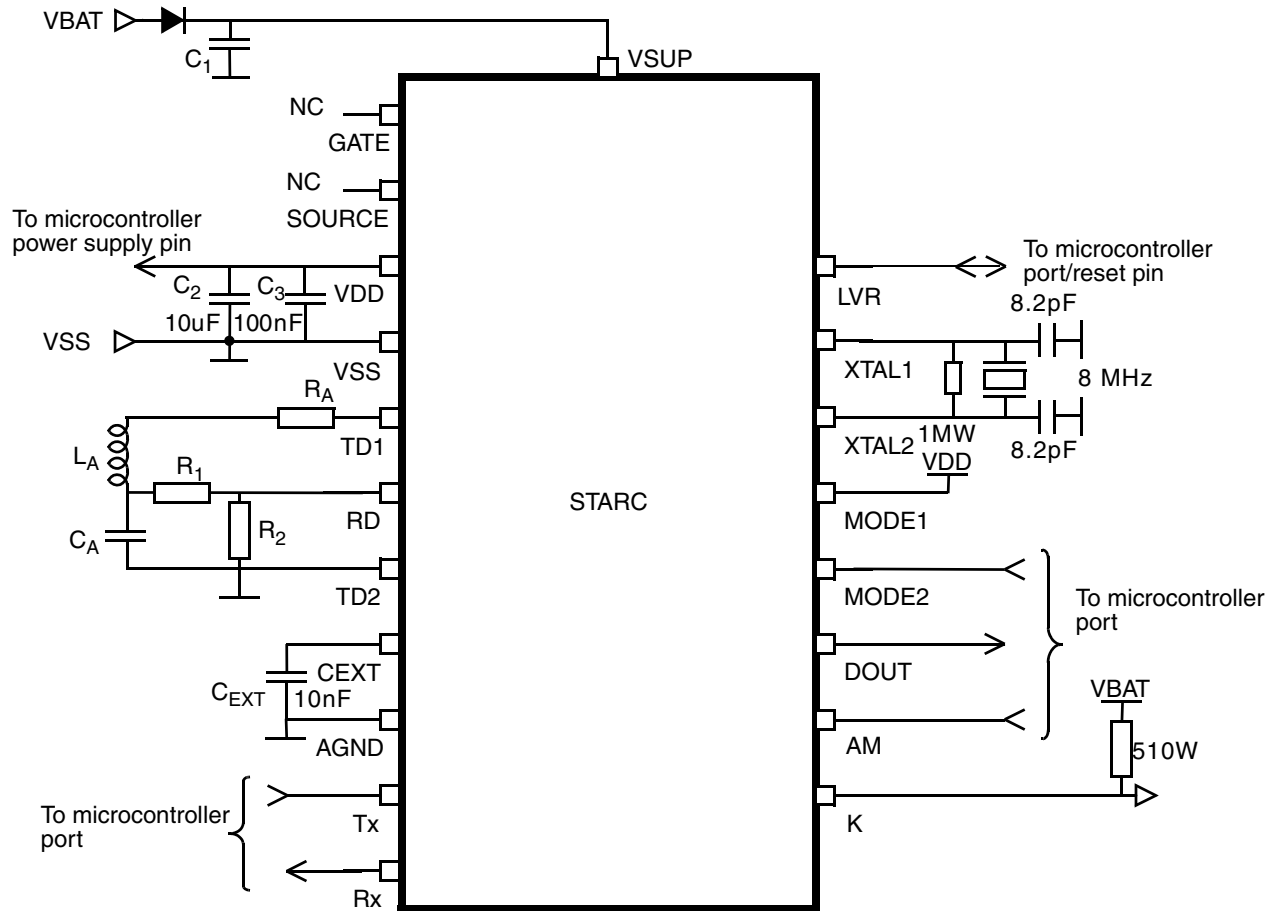

Figure 24. Standalone Configuration with One-Wire Bus

Application Schemes

Note: If no external MOS transistor is necessary to increase the voltage regulator current capability, the pins GATE and SOURCE must be left unconnected. C_1 is not required for the STARC functionality and only acts as a reservoir of energy. To preserve the demodulator sensitivity, C_{EXT} and R_2 should be connected to AGND and VSS connected to AGND using a low resistance path.

Figure 25. Standalone Configuration with Two-Wires Bus

Note: If no external MOS transistor is necessary to increase the voltage regulator current capability, the pins GATE and SOURCE must be left unconnected. C_1 is not required for the STARC functionality and only acts as a reservoir of energy. To preserve the demodulator sensitivity, C_{EXT} and R_2 should be connected to AGND and VSS connected to AGND using a low resistance path.

Information in this document is provided solely to enable system and software implementers to use Freescale Semiconductor products. There are no express or implied copyright licenses granted hereunder to design or fabricate any integrated circuits or integrated circuits based on the information in this document.

Freescale Semiconductor reserves the right to make changes without further notice to any products herein. Freescale Semiconductor makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does Freescale Semiconductor assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation consequential or incidental damages. "Typical" parameters that may be provided in Freescale Semiconductor data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals", must be validated for each customer application by customer's technical experts. Freescale Semiconductor does not convey any license under its patent rights nor the rights of others. Freescale Semiconductor products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the Freescale Semiconductor product could create a situation where personal injury or death may occur. Should Buyer purchase or use Freescale Semiconductor products for any such unintended or unauthorized application, Buyer shall indemnify and hold Freescale Semiconductor and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that Freescale Semiconductor was negligent regarding the design or manufacture of the part.

RoHS-compliant and/or Pb-free versions of Freescale products have the functionality and electrical characteristics as their non-RoHS-compliant and/or non-Pb-free counterparts. For further information, see <http://www.freescale.com> or contact your Freescale sales representative.
