# S29GL-N MirrorBit ${ }^{\oplus}$ Flash Family <br> S29GL064N, S29GL032N <br> 64 Megabit, 32 Megabit <br> 3.0-Volt only Page Mode Flash Memory <br> Featuring 110 nm MirrorBit Process Technology <br> Data Sheet 

Notice to Readers: This document states the current technical specifications regarding the Spansion product(s) described herein. Each product described herein may be designated as Advance Information, Preliminary, or Full Production. See Notice On Data Sheet Designations for definitions.

## Notice On Data Sheet Designations

Spansion Inc. issues data sheets with Advance Information or Preliminary designations to advise readers of product information or intended specifications throughout the product life cycle, including development, qualification, initial production, and full production. In all cases, however, readers are encouraged to verify that they have the latest information before finalizing their design. The following descriptions of Spansion data sheet designations are presented here to highlight their presence and definitions.

## Advance Information

The Advance Information designation indicates that Spansion Inc. is developing one or more specific products, but has not committed any design to production. Information presented in a document with this designation is likely to change, and in some cases, development on the product may discontinue. Spansion Inc. therefore places the following conditions upon Advance Information content:
"This document contains information on one or more products under development at Spansion Inc. The information is intended to help you evaluate this product. Do not design in this product without contacting the factory. Spansion Inc. reserves the right to change or discontinue work on this proposed product without notice."

## Preliminary

The Preliminary designation indicates that the product development has progressed such that a commitment to production has taken place. This designation covers several aspects of the product life cycle, including product qualification, initial production, and the subsequent phases in the manufacturing process that occur before full production is achieved. Changes to the technical specifications presented in a Preliminary document should be expected while keeping these aspects of production under consideration. Spansion places the following conditions upon Preliminary content:

> "This document states the current technical specifications regarding the Spansion product(s) described herein. The Preliminary status of this document indicates that product qualification has been completed, and that initial production has begun. Due to the phases of the manufacturing process that require maintaining efficiency and quality, this document may be revised by subsequent versions or modifications due to changes in technical specifications."

## Combination

Some data sheets contain a combination of products with different designations (Advance Information, Preliminary, or Full Production). This type of document distinguishes these products and their designations wherever necessary, typically on the first page, the ordering information page, and pages with the DC Characteristics table and the AC Erase and Program table (in the table notes). The disclaimer on the first page refers the reader to the notice on this page.

## Full Production (No Designation on Document)

When a product has been in production for a period of time such that no changes or only nominal changes are expected, the Preliminary designation is removed from the data sheet. Nominal changes may include those affecting the number of ordering part numbers available, such as the addition or deletion of a speed option, temperature range, package type, or $\mathrm{V}_{\mathrm{IO}}$ range. Changes may also include those needed to clarify a description or to correct a typographical error or incorrect specification. Spansion Inc. applies the following conditions to documents in this category:
"This document states the current technical specifications regarding the Spansion product(s) described herein. Spansion Inc. deems the products to have been in sufficient production volume such that subsequent versions of this document are not expected to change. However, typographical or specification corrections, or modifications to the valid combinations offered may occur."

Questions regarding these document designations may be directed to your local sales office.

# S29GL-N MirrorBit ${ }^{\ominus}$ Flash Family <br> S29GL064N, S29GL032N <br> 64 Megabit, 32 Megabit <br> 3.0 Volt-only Page Mode Flash Memory <br> Featuring 110 nm MirrorBit Process Technology <br> Data Sheet 

## Distinctive Characteristics

## Architectural Advantages

- Single power supply operation
- Manufactured on 110 nm MirrorBit process technology
- Secured Silicon Sector region
- 128-word/256-byte sector for permanent, secure identification through an 8-word/16-byte random Electronic Serial Number, accessible through a command sequence
- Programmed and locked at the factory or by the customer

■ Flexible sector architecture

- 64 Mb (uniform sector models): One hundred twenty-eight 32 Kword ( 64 KB ) sectors
-64 Mb (boot sector models): One hundred twenty-seven 32 Kword ( 64 KB ) sectors + eight 4Kword (8KB) boot sectors
-32 Mb (uniform sector models): Sixty-four 32Kword ( 64 KB ) sectors
-32 Mb (boot sector models): Sixty-three 32Kword ( 64 KB ) sectors + eight 4Kword (8KB) boot sectors
- Enhanced Versatilel/O" Control
- All input levels (address, control, and DQ input levels) and outputs are determined by voltage on $\mathrm{V}_{10}$ input. $\mathrm{V}_{1 \mathrm{O}}$ range is 1.65 to $\mathrm{V}_{\mathrm{CC}}$
■ Compatibility with JEDEC standards
- Provides pinout and software compatibility for single-power supply flash, and superior inadvertent write protection
- 100,000 erase cycles typical per sector
- 20-year data retention typical

## Performance Characteristics

## - High performance

- 90 ns access time
- 8-word/16-byte page read buffer
-25 ns page read time
- 16-word/32-byte write buffer which reduces overall programming time for multiple-word updates
- Low power consumption
- 25 mA typical initial read current,

1 mA typical page read current

- 50 mA typical erase/program current
$-1 \mu \mathrm{~A}$ typical standby mode current

## - Package options

- 48-pin TSOP
- 56-pin TSOP
- 64-ball Fortified BGA
- 48-ball fine-pitch BGA

## Software \& Hardware Features

## - Software features

- Advanced Sector Protection: offers Persistent Sector Protection and Password Sector Protection
- Program Suspend \& Resume: read other sectors before programming operation is completed
- Erase Suspend \& Resume: read/program other sectors before an erase operation is completed
- Data\# polling \& toggle bits provide status
- CFI (Common Flash Interface) compliant: allows host system to identify and accommodate multiple flash devices
- Unlock Bypass Program command reduces overall multiple-word programming time
■ Hardware features
- WP\#/ACC input accelerates programming time (when high voltage is applied) for greater throughput during system production. Protects first or last sector regardless of sector protection settings on uniform sector models
- Hardware reset input (RESET\#) resets device
- Ready/Busy\# output (RY/BY\#) detects program or erase cycle completion

## General Description

The S29GL-N family of devices are 3.0-Volt single-power Flash memory manufactured using 110 nm MirrorBit technology. The S29GL064N is a 64-Mb device organized as 4,194,304 words or $8,388,608$ bytes. The S29GL032N is a 32-Mb device organized as $2,097,152$ words or $4,194,304$ bytes. Depending on the model number, the devices have 16-bit wide data bus only, or a 16-bit wide data bus that can also function as an 8 -bit wide data bus by using the BYTE\# input. The devices can be programmed either in the host system or in standard EPROM programmers.
Access times as fast as 90 ns are available. Note that each access time has a specific operating voltage range ( $\mathrm{V}_{\mathrm{CC}}$ ) as specified in the Product Selector Guide and the Ordering Information-S29GL032N, and Ordering Information-S29GL064N. Package offerings include 48-pin TSOP, 56-pin TSOP, 48-ball fine-pitch BGA and 64-ball Fortified BGA, depending on model number. Each device has separate chip enable (CE\#), write enable (WE\#) and output enable (OE\#) controls.

Each device requires only a single 3.0-Volt power supply for both read and write functions. In addition to a $V_{C C}$ input, a high-voltage accelerated program (ACC) feature provides shorter programming times through increased voltage on the WP\#/ACC or ACC input. This feature is intended to facilitate factory throughput during system production, but may also be used in the field if desired.

The device is entirely command set compatible with the JEDEC single-power-supply Flash standard. Commands are written to the device using standard microprocessor write timing. Write cycles also internally latch addresses and data needed for the programming and erase operations.

The sector erase architecture allows memory sectors to be erased and reprogrammed without affecting the data contents of other sectors. The device is fully erased when shipped from the factory.
The Advanced Sector Protection features several levels of sector protection, which can disable both the program and erase operations in certain sectors. Persistent Sector Protection is a method that replaces the previous 12 -volt controlled protection method. Password Sector Protection is a highly sophisticated protection method that requires a password before changes to certain sectors are permitted.
Device programming and erasure are initiated through command sequences. Once a program or erase operation begins, the host system need only poll the DQ7 (Data\# Polling) or DQ6 (toggle) status bits or monitor the Ready/Busy\# (RY/BY\#) output to determine whether the operation is complete. To facilitate programming, an Unlock Bypass mode reduces command sequence overhead by requiring only two write cycles to program data instead of four.

Hardware data protection measures include a low $\mathrm{V}_{\mathrm{CC}}$ detector that automatically inhibits write operations during power transitions. The hardware sector protection feature disables both program and erase operations in any combination of sectors of memory. This can be achieved in-system or via programming equipment.

The Erase Suspend/Erase Resume feature allows the host system to pause an erase operation in a given sector to read or program any other sector and then complete the erase operation. The Program Suspend/ Program Resume feature enables the host system to pause a program operation in a given sector to read any other sector and then complete the program operation.
The hardware RESET\# pin terminates any operation in progress and resets the device, after which it is then ready for a new operation. The RESET\# pin may be tied to the system reset circuitry. A system reset would thus also reset the device, enabling the host system to read boot-up firmware from the Flash memory device.

The device reduces power consumption in the standby mode when it detects specific voltage levels on CE\# and RESET\#, or when addresses are stable for a specified period of time.

The Write Protect (WP\#) feature protects the first or last sector by asserting a logic low on the WP\#/ACC pin or WP\# pin, depending on model number. The protected sector is still protected even during accelerated programming.
The Secured Silicon Sector provides a 128-word/256-byte area for code or data that can be permanently protected. Once this sector is protected, no further changes within the sector can occur.
Spansion MirrorBit flash technology combines years of Flash memory manufacturing experience to produce the highest levels of quality, reliability and cost effectiveness. The device electrically erases all bits within a sector simultaneously via hot-hole assisted erase. The data is programmed using hot electron injection.

## Special Package Handling Instructions

Special handling is required for Flash Memory products in molded packages (TSOP and BGA). The package and/or data integrity may be compromised if the package body is exposed to temperatures above $150^{\circ} \mathrm{C}$ for prolonged periods of time.

|  | 11 |  | V1, V2 |  |  |  |

## Notes

1. Type 0 is standard. Specify others as required: TSOPs can be packed in Types 0 and 3; BGAs can be packed in Types 0, 2, or 3.
2. TSOP package marking omits packing type designator from ordering part number.
3. BGA package marking omits leading S29 and packing type designator from ordering part number.
4. Contact local sales for availability for Leaded lead-frame parts.

## 7. Ordering Information-S29GL064N

## S29GL064N Standard Products

Standard products are available in several packages and operating ranges. The order number (Valid Combination) is formed by a combination of the following:

DEVICE NUMBER/DESCRIPTION
S29GL064N, 64 Megabit Page-Mode Flash Memory
Manufactured using 110 nm MirrorBit ${ }^{\circledR}$ Process Technology, 3.0 Volt-only Read, Program, and Erase

### 7.1 Valid Combinations

| S29GL064N Valid Combinations |  |  |  |  | Package Description |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Device Number | Speed Option | Package, Material, \& Temperature Range | Model Number | Packing Type |  |  |
| S29GL064N | 90 | TFI | 03, 04, 06, 07 | 0,2,3 (Note 1) | TS048 (Note 2) | TSOP |
|  | 11 |  | V6, V7 |  |  |  |
|  | 90 |  | 01, 02 |  | 056 |  |
|  | 11 |  | V1, V2 |  | (Note 2) |  |
|  | 90 | BFI | 03, 04 |  | VBK048 (Note 3) | Fine-Pitch BGA |
|  | 90 | FFI | 01, 02, 03, 04 |  | LAA064 (Note 3) | Fortified BGA |
|  | 11 |  | V1, V2 |  |  |  |
|  | 90 | DFI | 01, 02, 03, 04 |  | LAE064 (Note 3) |  |
|  | 11 |  | V1, V2 |  |  |  |

## Notes

1. Type 0 is standard. Specify others as required: TSOPs can be packed in Types 0 and 3; BGAs can be packed in Types 0,2 , or 3 .
2. TSOP package marking omits packing type designator from ordering part number.
3. BGA package marking omits leading S29 and packing type designator from ordering part number.
4. Contact local sales for availability for Leaded lead-frame parts.

## 8. Device Bus Operations

This section describes the requirements and use of the device bus operations, which are initiated through the internal command register. The command register itself does not occupy any addressable memory location. The register is a latch used to store the commands, along with the address and data information needed to execute the command. The contents of the register serve as inputs to the internal state machine. The state machine outputs dictate the function of the device. Table 8.1 lists the device bus operations, the inputs and control levels they require, and the resulting output. The following subsections describe each of these operations in further detail.

Table 8.1 Device Bus Operations

| Operation | CE\# | OE\# | WE\# | RESET\# | WP\# | ACC | Addresses | $\begin{gathered} \text { DQ0- } \\ \text { DQ7 } \end{gathered}$ | DQ8-DQ15 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |  |  | $\begin{aligned} & \text { BYTE\# } \\ & =V_{\mathrm{IH}} \end{aligned}$ | $\begin{aligned} & \text { BYTE\# } \\ & =V_{\mathrm{IL}} \end{aligned}$ |

X = Don't Care
$A_{I N}=$ Address In
$D_{I N}=$ Data In
$D_{\text {Out }}=$ Data Out

## Notes

1. If WP\# = $V_{I L}$, the first or last sector remains protected (for uniform sector devices), and the two outer boot sectors are protected (for boot sector devices). If WP\# $=$ VIH, the first or last sector, or the two outer boot sectors are protected or unprotected as determined by the method described in Write Protect (WP\#). All sectors are unprotected when shipped from the factory (The Secured Silicon Sector may be factory protected depending on version ordered.)
2. $D_{I N}$ or $D_{\text {OUT }}$ as required by command sequence, data polling, or sector protect algorithm (see Figure 10.5 on page 56).

### 8.1 Word/Byte Configuration

The BYTE\# pin controls whether the device data I/O pins operate in the byte or word configuration. If the BYTE\# pin is set at logic 1, the device is in word configuration, DQ0-DQ15 are active and controlled by CE\#, WE\# and OE\#.

If the BYTE\# pin is set at logic 0 , the device is in byte configuration, and only data I/O pins DQ0-DQ7 are active and controlled by CE\#, WE\# and OE\#. The data I/O pins DQ8-DQ14 are tri-stated, and the DQ15 pin is used as an input for the LSB (A-1) address function.

### 8.2 Requirements for Reading Array Data

All memories require access time to output array data. In a read operation, data is read from one memory location at a time. Addresses are presented to the device in random order, and the propagation delay through the device causes the data on its outputs to arrive with the address on its inputs.

The device defaults to reading array data after device power-up or hardware reset. To read data from the memory array, the system must first assert a valid address on Amax-A0, while driving OE\# and CE\# to $\mathrm{V}_{\mathrm{IL}}$. WE\# must remain at $\mathrm{V}_{\mathrm{IH}}$. All addresses are latched on the falling edge of CE\#. Data will appear on DQ15-DQ0 after address access time ( $\mathrm{t}_{\mathrm{ACC}}$ ), which is equal to the delay from stable addresses to valid output data. The OE\# signal must be driven to $\mathrm{V}_{\mathrm{IL}}$. Data is output on DQ15-DQ0 pins after the access time ( $\mathrm{t}_{\mathrm{OE}}$ ) has elapsed from the falling edge of OE\#.
See Reading Array Data on page 41 for more information. Refer to Table 15.1 on page 64 for timing specifications and the timing diagram. Refer to Table 13.1 on page 62 for the active current specification on reading array data.

### 8.2.1 Page Mode Read

The device is capable of fast page mode read and is compatible with the page mode Mask ROM read operation. This mode provides faster read access speed for random locations within a page. The page size of the device is 8 words/16 bytes. The appropriate page is selected by the higher address bits $\mathrm{A}(\mathrm{max})-\mathrm{A} 3$. Address bits A2-A0 in word mode (A2-A-1 in byte mode) determine the specific word within a page. This is an asynchronous operation; the microprocessor supplies the specific word location.
The random or initial page access is equal to $t_{A C C}$ or $t_{C E}$ and subsequent page read accesses (as long as the locations specified by the microprocessor falls within that page) is equivalent to $t_{\text {PACC }}$. When CE\# is deasserted and reasserted for a subsequent access, the access time is $t_{A C C}$ or $t_{C E}$. Fast page mode accesses are obtained by keeping the read-page addresses constant and changing the intra-read page addresses.

### 8.3 Writing Commands/Command Sequences

To write a command or command sequence (which includes programming data to the device and erasing sectors of memory), the system must drive WE\# and CE\# to $\mathrm{V}_{\mathrm{IL}}$, and OE \# to $\mathrm{V}_{\mathrm{IH}}$.
The device features an Unlock Bypass mode to facilitate faster programming. Once the device enters the Unlock Bypass mode, only two write cycles are required to program a word, instead of four. The Word Program Command Sequence on page 42 contains details on programming data to the device using both standard and Unlock Bypass command sequences.
An erase operation can erase one sector, multiple sectors, or the entire device. Tables 8.2-8.8 indicate the address space that each sector occupies.
Refer to the DC Characteristics table for the active current specification for the write mode. The AC Characteristics section contains timing specification tables and timing diagrams for write operations.

### 8.3.1 Write Buffer

Write Buffer Programming allows the system write to a maximum of 16 words/32 bytes in one programming operation. This results in faster effective programming time than the standard programming algorithms.

### 8.3.2 Accelerated Program Operation

The device offers accelerated program operations through the ACC function. This is one of two functions provided by the WP\#/ACC or ACC pin, depending on model number. This function is primarily intended to allow faster manufacturing throughput at the factory.

If the system asserts $\mathrm{V}_{\mathrm{HH}}$ on this pin, the device automatically enters the Unlock Bypass mode, temporarily unprotects any protected sectors, and uses the higher voltage on the pin to reduce the time required for program operations. The system would use a two-cycle program command sequence as required by the Unlock Bypass mode. Removing $\mathrm{V}_{\mathrm{HH}}$ from the WP\#/ACC or ACC pin, depending on model number, returns the device to normal operation. Note that the WP\#/ACC or ACC pin must not be at $V_{H H}$ for operations other than accelerated programming, or device damage may result. WP\# contains an internal pull-up; when unconnected, WP\# is at $V_{I H}$.

### 8.3.3 Autoselect Functions

If the system writes the autoselect command sequence, the device enters the autoselect mode. The system can then read autoselect codes from the internal register (which is separate from the memory array) on DQ7-DQ0. Standard read cycle timings ( $\mathrm{t}_{\mathrm{ACC}}$ ) apply in this mode. Refer to Autoselect Mode on page 29 and Autoselect Command Sequence on page 42 for more information.

### 8.4 Standby Mode

When the system is not reading or writing to the device, it can be placed in to standby mode. In this mode, current consumption is greatly reduced, and the outputs are placed in the high impedance state, independent of the OE\# input.

The device enters the CMOS standby mode when the CE\# and RESET\# pins are both held at $\mathrm{V}_{\mathrm{IO}} \pm 0.3 \mathrm{~V}$. (Note that this is a more restricted voltage range than $\mathrm{V}_{\mathrm{IH}}$.) If $\mathrm{CE} \#$ and RESET\# are held at $\mathrm{V}_{\mathrm{IH}}$, but not within $\mathrm{V}_{\mathrm{IO}} \pm 0.3 \mathrm{~V}$, the device is in the standby mode, but the standby current is greater. The device requires standard access time ( $\mathrm{t}_{\mathrm{ACC}} / \mathrm{t}_{\mathrm{CE}}$ ) for read access when the device is in either of these standby modes, before it is ready to read data.
If the device is deselected during erasure or programming, the device draws active current until the operation is completed.

Refer to the DC Characteristics on page 62 for the standby current specification.

### 8.5 Automatic Sleep Mode

The automatic sleep mode minimizes Flash device energy consumption. The device automatically enables this mode when addresses remain stable for $\mathrm{t}_{\text {ACC }}+30 \mathrm{~ns}$. The automatic sleep mode is independent of the CE\#, WE\#, and OE\# control signals. Standard address access timings provide new data when addresses are changed. While in sleep mode, output data is latched and always available to the system. Refer to the $D C$ Characteristics on page 62 for the automatic sleep mode current specification.

### 8.6 RESET\#: Hardware Reset Pin

The RESET\# pin provides a hardware method of resetting the device to reading array data. When the RESET\# pin is driven low for at least a period of $t_{R P}$, the device immediately terminates any operation in progress, output pins go to $\mathrm{Hi}-\mathrm{Z}$, and all read/write commands are ignored for the duration of the RESET\# pulse. Program/Erase operations that were interrupted should be reinitiated once the device is ready to accept another command sequence, to ensure data integrity.

Current is reduced for the duration of the RESET\# pulse. When RESET\# is held at $\mathrm{V}_{S S} \pm 0.3 \mathrm{~V}$, the device draws CMOS standby current ( $\mathrm{I}_{\mathrm{CC} 5}$ ).
The RESET\# pin may be tied to the system reset circuitry. A system reset would thus also reset the Flash memory, enabling the system to read the boot-up firmware from the Flash memory.
Refer to the AC Characteristics tables for RESET\# parameters and to Figure 15.4 on page 66 for the timing diagram.

### 8.7 Output Disable Mode

When the $O E \#$ input is at $\mathrm{V}_{I H}$, output from the device is disabled. The output pins are placed in a high impedance state.

Table 8.2 S29GL032N (Models 01, 02, V1, V2) Sector Addresses

| Sector | A20-A15 | Sector Size (KB/ Kwords) | 8-bit <br> Address Range | 16-bit <br> Address Range | Sector | A20-A15 | Sector Size (KB/ Kwords) | 8-bit <br> Address Range | 16-bit <br> Address Range |

### 8.8 Autoselect Mode

The autoselect mode provides manufacturer and device identification, and sector protection verification, through identifier codes output on DQ7-DQ0. This mode is primarily intended for programming equipment to automatically match a device to be programmed with its corresponding programming algorithm. However, the autoselect codes can also be accessed in-system through the command register.

When using programming equipment, the autoselect mode requires $\mathrm{V}_{\mathrm{ID}}$ on address pin A 9 . Address pins A 6 , A3, A2, A1, and A0 must be as shown in Table 8.9 on page 29. In addition, when verifying sector protection, the sector address must appear on the appropriate highest order address bits (see Table 8.2 - Table 8.8). Table 8.9 shows the remaining address bits that are don't care. When all necessary bits are set as required, the programming equipment may then read the corresponding identifier code on DQ7-DQ0.
To access the autoselect codes in-system, the host system can issue the autoselect command via the command register, as shown in Table 10.1 on page 51 and Table 10.3 on page 53. This method does not require $\mathrm{V}_{\mathrm{ID}}$. Refer to the Autoselect Command Sequence section for more information.

## Legend

$L=$ Logic Low $=V_{I L}$
$H=$ Logic High $=V_{I H}$
SA = Sector Address
$X=$ Don't care

### 8.9 Advanced Sector Protection

The device features several levels of sector protection, which can disable both the program and erase operations in certain sectors:

### 8.9.1 Persistent Sector Protection

A command sector protection method that replaces the old 12 V controlled protection method.

### 8.9.2 Password Sector Protection

A highly sophisticated protection method that requires a password before changes to certain sectors are permitted

### 8.9.3 WP\# Hardware Protection

A write protect pin that can prevent program or erase operations in the outermost sectors.
The WP\# Hardware Protection feature is always available, independent of the software managed protection method chosen.

### 8.9.4 Selecting a Sector Protection Mode

All parts default to operate in the Persistent Sector Protection mode. The user must then choose if the Persistent or Password Protection method is most desirable. There are two one-time programmable nonvolatile bits that define which sector protection method is used. If the user decides to continue using the Persistent Sector Protection method, they must set the Persistent Sector Protection Mode Locking Bit. This permanently sets the part to operate only using Persistent Sector Protection. If the user decides to use the password method, they must set the Password Mode Locking Bit. This permanently sets the part to operate only using password sector protection.
It is important to remember that setting either the Persistent Sector Protection Mode Locking Bit or the Password Mode Locking Bit permanently selects the protection mode. It is not possible to switch between the two methods once a locking bit is set. It is important that one mode is explicitly selected when the device is first programmed, rather than relying on the default mode alone. This is so that it is not possible for a system program or virus to later set the Password Mode Locking Bit, which would cause an unexpected shift from the default Persistent Sector Protection Mode into the Password Protection Mode.
The device is shipped with all sectors unprotected. Spansion offers the option of programming and protecting sectors at the factory prior to shipping the device through the ExpressFlash ${ }^{\text {TM }}$ Service. Contact your sales representative for details.
It is possible to determine whether a sector is protected or unprotected. See Autoselect Command Sequence on page 42 for details.

### 8.10 Lock Register

The Lock Register consists of 3 bits (DQ2, DQ1, and DQ0). These DQ2, DQ1, DQ0 bits of the Lock Register are programmable by the user. Users are not allowed to program both DQ2 and DQ1 bits of the Lock Register to the 00 state. If the user tries to program DQ2 and DQ1 bits of the Lock Register to the 00 state, the device aborts the Lock Register back to the default 11 state. The programming time of the Lock Register is same as the typical word programming time ( $\mathrm{t}_{\mathrm{WH} W \mathrm{WH}_{1} \text { ) }}$ without utilizing the Write Buffer of the device. During a Lock Register programming sequence execution, the DQ6 Toggle Bit I toggles until the programming of the Lock Register has completed to indicate programming status. All Lock Register bits are readable to allow users to verify Lock Register statuses.

The Customer Secured Silicon Sector Protection Bit is DQ0, Persistent Protection Mode Lock Bit is DQ1, and Password Protection Mode Lock Bit is DQ2 are accessible by all users. Each of these bits are non-volatile. DQ15-DQ3 are reserved and must be 1's when the user tries to program the DQ2, DQ1, and DQ0 bits of the Lock Register. The user is not required to program DQ2, DQ1 and DQ0 bits of the Lock Register at the same time. This allows users to lock the Secured Silicon Sector and then set the device either permanently into Password Protection Mode or Persistent Protection Mode and then lock the Secured Silicon Sector at separate instances and time frames.

■ Secured Silicon Sector Protection allows the user to lock the Secured Silicon Sector area
■ Persistent Protection Mode Lock Bit allows the user to set the device permanently to operate in the Persistent Protection Mode

■ Password Protection Mode Lock Bit allows the user to set the device permanently to operate in the Password Protection Mode

Table 8.10 Lock Register

| DQ15-3 | DQ2 | DQ1 | DQ0 |
| :---: | :---: | :---: | :---: |
| Don't Care | Password Protection Mode <br> Lock Bit | Persistent Protection Mode <br> Lock Bit | Secured Silicon Sector <br> Protection Bit |

### 8.11 Persistent Sector Protection

The Persistent Sector Protection method replaces the old 12 V controlled protection method while at the same time enhancing flexibility by providing three different sector protection states

| Dynamically Locked | The sector is protected and can be changed by a simple command |
| :--- | :--- |
| Persistently Locked | A sector is protected and cannot be changed |
| Unlocked | The sector is unprotected and can be changed by a simple command |

To achieve these states, three types of "bits" are used:

### 8.11.1 Dynamic Protection Bit (DYB)

A volatile protection bit is assigned for each sector. After power-up or hardware reset, the contents of all DYB bits are in the "unprotected state". Each DYB is individually modifiable through the DYB Set Command and DYB Clear Command. The DYB bits and Persistent Protect Bits (PPB) Lock bit are defaulted to power up in the cleared state or unprotected state - meaning the all PPB bits are changeable.

The Protection State for each sector is determined by the logical OR of the PPB and the DYB related to that sector. For the sectors that have the PPB bits cleared, the DYB bits control whether or not the sector is protected or unprotected. By issuing the DYB Set and DYB Clear command sequences, the DYB bits is protected or unprotected, thus placing each sector in the protected or unprotected state. These are the socalled Dynamic Locked or Unlocked states. They are called dynamic states because it is very easy to switch back and forth between the protected and un-protected conditions. This allows software to easily protect sectors against inadvertent changes yet does not prevent the easy removal of protection when changes are needed.

The DYB bits maybe set or cleared as often as needed. The PPB bits allow for a more static, and difficult to change, level of protection. The PPB bits retain their state across power cycles because they are Non-

Volatile. Individual PPB bits are set with a program command but must all be cleared as a group through an erase command.
The PPB Lock Bit adds an additional level of protection. Once all PPB bits are programmed to the desired settings, the PPB Lock Bit may be set to the "freeze state". Setting the PPB Lock Bit to the "freeze state" disables all program and erase commands to the Non-Volatile PPB bits. In effect, the PPB Lock Bit locks the PPB bits into their current state. The only way to clear the PPB Lock Bit to the "unfreeze state" is to go through a power cycle, or hardware reset. The Software Reset command does not clear the PPB Lock Bit to the "unfreeze state". System boot code can determine if any changes to the PPB bits are needed e.g. to allow new system code to be downloaded. If no changes are needed then the boot code can set the PPB Lock Bit to disable any further changes to the PPB bits during system operation.
The WP\# write protect pin adds a final level of hardware protection. When this pin is low it is not possible to change the contents of the WP\# protected sectors. These sectors generally hold system boot code. So, the WP\# pin can prevent any changes to the boot code that could override the choices made while setting up sector protection during system initialization.
It is possible to have sectors that have been persistently locked, and sectors that are left in the dynamic state. The sectors in the dynamic state are all unprotected. If there is a need to protect some of them, a simple DYB Set command sequence is all that is necessary. The DYB Set and DYB Clear commands for the dynamic sectors switch the DYB bits to signify protected and unprotected, respectively. If there is a need to change the status of the persistently locked sectors, a few more steps are required. First, the PPB Lock Bit must be disabled to the "unfreeze state" by either putting the device through a power-cycle, or hardware reset. The PPB bits can then be changed to reflect the desired settings. Setting the PPB Lock Bit once again to the "freeze state" locks the PPB bits, and the device operates normally again.
To achieve the best protection, execute the PPB Lock Bit Set command early in the boot code, and protect the boot code by holding WP\# $=\mathrm{V}_{\mathrm{IL}}$.

### 8.11.2 Persistent Protection Bit (PPB)

A single Persistent (non-volatile) Protection Bit is assigned to each sector. If a PPB is programmed to the protected state through the "PPB Program" command, that sector is protected from program or erase operations and is therefor read-only. If a PPB requires erasure, all of the sector PPB bits must first be erased in parallel through the "All PPB Erase" command. The "All PPB Erase" command preprograms all PPB bits prior to PPB erasing. All PPB bits erase in parallel, unlike programming where individual PPB bits are programmable. The PPB bits are limited to the same number of cycles as a flash memory sector.
Programming the PPB bit requires the typical word programming time without utilizing the Write Buffer. During a PPB bit programming and all PPB bit erasing sequence executions, the DQ6 Toggle Bit I toggles until the programming of the PPB bit or erasing of all PPB bits has completed to indicate programming and erasing status. Erasing all of the PPB bits at once requires typical sector erase time. During the erasing of all PPB bits, the DQ3 Sector Erase Timer bit outputs a 1 to indicate the erasure of all PPB bits are in progress. When the erasure of all PPB bits has completed, the DQ3 Sector Erase Timer bit outputs a 0 to indicate that all PPB bits have been erased. Reading the PPB Status bit requires the initial access time of the device.

### 8.11.3 Persistent Protection Bit Lock (PPB Lock Bit)

A global volatile bit. When set to the "freeze state", the PPB bits cannot be changed. When cleared to the "unfreeze state", the PPB bits are changeable. There is only one PPB Lock Bit per device. The PPB Lock Bit is cleared to the "unfreeze state" at power-up or hardware reset. There is no command sequence to unlock or "unfreeze" the PPB Lock Bit.

Configuring the PPB Lock Bit to the freeze state requires approximately 100ns. Reading the PPB Lock Status bit requires the initial access time ( $\mathrm{t}_{\mathrm{ACC}}$ ) of the device.

Table 8.11 Sector Protection Schemes

| Protection States |  |  | Sector State |
| :---: | :---: | :---: | :--- |
| DYB Bit | PPB Bit | PPB Lock Bit |  |
| Unprotect | Unprotect | Unfreeze | Unprotected - PPB and DYB are changeable |
| Unprotect | Unprotect | Freeze | Unprotected - PPB not changeable, DYB is changeable |
| Unprotect | Protect | Unfreeze | Protected - PPB and DYB are changeable |
| Unprotect | Protect | Freeze | Protected - PPB not changeable, DYB is changeable |
| Protect | Unprotect | Unfreeze | Protected - PPB and DYB are changeable |
| Protect | Unprotect | Freeze | Protected - PPB not changeable, DYB is changeable |
| Protect | Protect | Unfreeze | Protected - PPB and DYB are changeable |
| Protect | Protect | Freeze | Protected - PPB not changeable, DYB is changeable |

Table 8.11 contains all possible combinations of the DYB bit, PPB bit, and PPB Lock Bit relating to the status of the sector. In summary, if the PPB bit is set, and the PPB Lock Bit is set, the sector is protected and the protection cannot be removed until the next power cycle or hardware reset clears the PPB Lock Bit to "unfreeze state". If the PPB bit is cleared, the sector can be dynamically locked or unlocked. The DYB bit then controls whether or not the sector is protected or unprotected. If the user attempts to program or erase a protected sector, the device ignores the command and returns to read mode. A program command to a protected sector enables status polling for approximately $1 \mu$ s before the device returns to read mode without having modified the contents of the protected sector. An erase command to a protected sector enables status polling for approximately $50 \mu \mathrm{~s}$ after which the device returns to read mode without having erased the protected sector. The programming of the DYB bit, PPB bit, and PPB Lock Bit for a given sector can be verified by writing a DYB Status Read, PPB Status Read, and PPB Lock Status Read commands to the device.

The Autoselect Sector Protection Verification outputs the OR function of the DYB bit and PPB bit per sector basis. When the OR function of the DYB bit and PPB bit is a 1 , the sector is either protected by DYB or PPB or both. When the OR function of the DYB bit and PPB bit is a 0 , the sector is unprotected through both the DYB and PPB.

### 8.12 Password Sector Protection

The Password Sector Protection method allows an even higher level of security than the Persistent Sector Protection method. There are two main differences between the Persistent Sector Protection and the Password Sector Protection methods:

■ When the device is first powered on, or comes out of a reset cycle, the PPB Lock Bit is set to the locked state, or the freeze state, rather than cleared to the unlocked state, or the unfreeze state.
■ The only means to clear and unfreeze the PPB Lock Bit is by writing a unique 64-bit Password to the device.

The Password Sector Protection method is otherwise identical to the Persistent Sector Protection method.
A 64-bit password is the only additional tool utilized in this method.
The password is stored in a one-time programmable (OTP) region outside of the flash memory. Once the Password Protection Mode Lock Bit is set, the password is permanently set with no means to read, program, or erase it. The password is used to clear and unfreeze the PPB Lock Bit. The Password Unlock command must be written to the flash, along with a password. The flash device internally compares the given password with the pre-programmed password. If they match, the PPB Lock Bit is cleared to the unfreezed state, and the PPB bits can be altered. If they do not match, the flash device does nothing. There is a built-in $2 \mu \mathrm{~s}$ delay for each password check after the valid 64-bit password is entered for the PPB Lock Bit to be cleared to the "unfreezed state". This delay is intended to thwart any efforts to run a program that tries all possible combinations in order to crack the password.

### 8.13 Password and Password Protection Mode Lock Bit

In order to select the Password Sector Protection method, the user must first program the password. Spansion recommends that the password be somehow correlated to the unique Electronic Serial Number (ESN) of the particular flash device. Each ESN is different for every flash device; therefore each password should be different for every flash device. While programming in the password region, the customer may perform Password Read operations. Once the desired password is programmed in, the customer must then set the Password Protection Mode Lock Bit. This operation achieves two objectives:

1. It permanently sets the device to operate using the Password Protection Mode. It is not possible to reverse this function.
2. It also disables all further commands to the password region. All program, and read operations are ignored.
Both of these objectives are important, and if not carefully considered, may lead to unrecoverable errors. The user must be sure that the Password Sector Protection method is desired when programming the Password Protection Mode Lock Bit. More importantly, the user must be sure that the password is correct when the Password Protection Mode Lock Bit is programmed. Due to the fact that read operations are disabled, there is no means to read what the password is afterwards. If the password is lost after programming the Password Protection Mode Lock Bit, there is no way to clear and unfreeze the PPB Lock Bit. The Password Protection Mode Lock Bit, once programmed, prevents reading the 64-bit password on the DQ bus and further password programming. The Password Protection Mode Lock Bit is not erasable. Once Password Protection Mode Lock Bit is programmed, the Persistent Protection Mode Lock Bit is disabled from programming, guaranteeing that no changes to the protection scheme are allowed.

### 8.13.1 64-bit Password

The 64-bit Password is located in its own memory space and is accessible through the use of the Password Program and Password Read commands. The password function works in conjunction with the Password Protection Mode Lock Bit, which when programmed, prevents the Password Read command from reading the contents of the password on the pins of the device.

### 8.14 Persistent Protection Bit Lock (PPB Lock Bit)

A global volatile bit. The PPB Lock Bit is a volatile bit that reflects the state of the Password Protection Mode Lock Bit after power-up reset. If the Password Protection Mode Lock Bit is also programmed after programming the Password, the Password Unlock command must be issued to clear and unfreeze the PPB Lock Bit after a hardware reset (RESET\# asserted) or a power-up reset. Successful execution of the Password Unlock command clears and unfreezes the PPB Lock Bit, allowing for sector PPB bits to be modified. Without issuing the Password Unlock command, while asserting RESET\#, taking the device through a power-on reset, or issuing the PPB Lock Bit Set command sets the PPB Lock Bit to a the "freeze state".

If the Password Protection Mode Lock Bit is not programmed, the device defaults to Persistent Protection Mode. In the Persistent Protection Mode, the PPB Lock Bit is cleared to the unfreeze state after power-up or hardware reset. The PPB Lock Bit is set to the freeze state by issuing the PPB Lock Bit Set command. Once set to the freeze state the only means for clearing the PPB Lock Bit to the "unfreeze state" is by issuing a hardware or power-up reset. The Password Unlock command is ignored in Persistent Protection Mode.
Reading the PPB Lock Bit requires a 200 ns access time.

### 8.15 Secured Silicon Sector Flash Memory Region

The Secured Silicon Sector feature provides a Flash memory region that enables permanent part identification through an Electronic Serial Number (ESN). The Secured Silicon Sector is 256 bytes in length, and uses a Secured Silicon Sector Indicator Bit (DQ7) to indicate whether or not the Secured Silicon Sector is locked when shipped from the factory. This bit is permanently set at the factory and cannot be changed, which prevents cloning of a factory locked part. This ensures the security of the ESN once the product is shipped to the field.
The factory offers the device with the Secured Silicon Sector either customer lockable (standard shipping option) or factory locked (contact an AMD sales representative for ordering information). The customerlockable version is shipped with the Secured Silicon Sector unprotected, allowing customers to program the sector after receiving the device. The customer-lockable version also has the Secured Silicon Sector Indicator Bit permanently set to a 0 . The factory-locked version is always protected when shipped from the factory, and has the Secured Silicon Sector Indicator Bit permanently set to a 1. Thus, the Secured Silicon Sector Indicator Bit prevents customer-lockable devices from being used to replace devices that are factory locked.

The Secured Silicon sector address space in this device is allocated as follows:

| Secured Silicon Sector <br> Address Range | Customer Lockable | ESN Factory Locked | ExpressFlash <br> Factory Locked |
| :---: | :---: | :---: | :---: |
| $000000 \mathrm{~h}-000007 \mathrm{~h}$ | Determined by customer | ESN | ESN or determined by <br> customer |
| 000008h-00007Fh |  | Unavailable | Determined by customer |

The system accesses the Secured Silicon Sector through a command sequence (see Write Protect (WP\#/ ACC) on page 36). After the system has written the Enter Secured Silicon Sector command sequence, it may read the Secured Silicon Sector by using the addresses normally occupied by the first sector (SAO). This mode of operation continues until the system issues the Exit Secured Silicon Sector command sequence, or until power is removed from the device. On power-up, or following a hardware reset, the device reverts to sending commands to sector SAO.

### 8.15.1 Customer Lockable: Secured Silicon Sector NOT Programmed or Protected At the Factory

Unless otherwise specified, the device is shipped such that the customer may program and protect the 256byte Secured Silicon sector.
The system may program the Secured Silicon Sector using the write-buffer, accelerated and/or unlock bypass methods, in addition to the standard programming command sequence. See Command Definitions on page 41.
Programming and protecting the Secured Silicon Sector must be used with caution since, once protected, there is no procedure available for unprotecting the Secured Silicon Sector area and none of the bits in the Secured Silicon Sector memory space can be modified in any way.
The Secured Silicon Sector area can be protected using one of the following procedures:
■ Write the three-cycle Enter Secured Silicon Sector Region command.
■ To verify the protect/unprotect status of the Secured Silicon Sector, follow the algorithm.
Once the Secured Silicon Sector is programmed, locked and verified, the system must write the Exit Secured Silicon Sector Region command sequence to return to reading and writing within the remainder of the array.

### 8.15.2 Factory Locked: Secured Silicon Sector Programmed and Protected At the Factory

In devices with an ESN, the Secured Silicon Sector is protected when the device is shipped from the factory. The Secured Silicon Sector cannot be modified in any way. An ESN Factory Locked device has an 16-byte random ESN at addresses $000000 \mathrm{~h}-000007 \mathrm{~h}$. Please contact your sales representative for details on ordering ESN Factory Locked devices.

Customers may opt to have their code programmed by the factory through the ExpressFlash service (Express Flash Factory Locked). The devices are then shipped from the factory with the Secured Silicon Sector permanently locked. Contact your sales representative for details on using the ExpressFlash service.

### 8.16 Write Protect (WP\#/ACC)

The Write Protect function provides a hardware method of protecting the first or last sector without using $\mathrm{V}_{\text {ID }}$. Write Protect is one of two functions provided by the WP\#/ACC input.
If the system asserts $\mathrm{V}_{\mathrm{IL}}$ on the WP\#/ACC pin, the device disables program and erase functions in the first or last sector independently of whether those sectors were protected or unprotected. Note that if WP\#/ACC is at $\mathrm{V}_{\mathrm{IL}}$ when the device is in the standby mode, the maximum input load current is increased. See the table in $D C$ Characteristics on page 62.
If the system asserts $\mathrm{V}_{\mathrm{IH}}$ on the WP\#/ACC pin, the device reverts to whether the first or last sector was previously set to be protected or unprotected using the method described in Advanced Sector Protection on page 30. Note that WP\#/ACC contains an internal pull-up; when unconnected, WP\#/ACC is at $V_{I H}$.

### 8.17 Hardware Data Protection

The command sequence requirement of unlock cycles for programming or erasing provides data protection against inadvertent writes (refer to Table 10.1 on page 51 and Table 10.3 on page 53 for command definitions). In addition, the following hardware data protection measures prevent accidental erasure or programming, which might otherwise be caused by spurious system level signals during $\mathrm{V}_{\mathrm{CC}}$ power-up and power-down transitions, or from system noise.

### 8.17.1 Low $\mathrm{V}_{\mathrm{cc}}$ Write Inhibit

When $\mathrm{V}_{\mathrm{CC}}$ is less than $\mathrm{V}_{\mathrm{LKO}}$, the device does not accept any write cycles. This protects data during $\mathrm{V}_{\mathrm{CC}}$ power-up and power-down. The command register and all internal program/erase circuits are disabled, and the device resets to the read mode. Subsequent writes are ignored until $\mathrm{V}_{\mathrm{CC}}$ is greater than $\mathrm{V}_{\mathrm{LKO}}$. The system must provide the proper signals to the control pins to prevent unintentional writes when $\mathrm{V}_{\mathrm{CC}}$ is greater than $\mathrm{V}_{\text {LKO }}$.

### 8.17.2 Write Pulse Glitch Protection

Noise pulses of less than 3 ns (typical) on OE\#, CE\# or WE\# do not initiate a write cycle.

### 8.17.3 Logical Inhibit

Write cycles are inhibited by holding any one of $\mathrm{OE} \#=\mathrm{V}_{\mathrm{IL}}, \mathrm{CE} \#=\mathrm{V}_{\mathrm{IH}}$ or $\mathrm{WE} \#=\mathrm{V}_{\mathrm{IH}}$. To initiate a write cycle, CE\# and WE\# must be a logical zero while OE\# is a logical one.

### 8.17.4 Power-Up Write Inhibit

If WE\# $=\mathrm{CE} \#=\mathrm{V}_{\mathrm{IL}}$ and $\mathrm{OE} \#=\mathrm{V}_{\mathrm{IH}}$ during power up, the device does not accept commands on the rising edge of WE\#. The internal state machine is automatically reset to the read mode on power-up.

## 9. Common Flash Memory Interface (CFI)

The Common Flash Interface (CFI) specification outlines device and host system software interrogation handshake, which allows specific vendor-specified software algorithms to be used for entire families of devices. Software support can then be device-independent, JEDEC ID-independent, and forward- and backward-compatible for the specified flash device families. Flash vendors can standardize their existing interfaces for long-term compatibility.

This device enters the CFI Query mode when the system writes the CFI Query command, 98h, to address 55 h , any time the device is ready to read array data. The system can read CFI information at the addresses given in Table 9.1 on page 37 - Table 9.4 on page 40. To terminate reading CFI data, the system must write the reset command.

The system can also write the CFI query command when the device is in the autoselect mode. The device enters the CFI query mode, and the system can read CFI data at the addresses given in Table 9.1 on page 37 - Table 9.4 on page 40 . The system must write the reset command to return the device to reading array data.

For further information, please refer to the CFI Specification and CFI Publication 100. Alternatively, contact your sales representative for copies of these documents.

Table 9.1 CFI Query Identification String

| Addresses (x16) | Addresses (x8) | Data | Description |
| :---: | :---: | :---: | :--- |
| 10 h | 20 h | 0051 h |  |
| 11 h | 22 h | 0052 h | Query Unique ASCII string "QRY" |
| 12 h | 24 h | 0059 h |  |
| 13 h | 26 h | 0002 h | Primary OEM Command Set |
| 14 h | 28 h | 0000 h |  |
| 15 h | 2 h | 0040 h | Address for Primary Extended Table |
| 16 h | 2 Ch | 0000 h |  |
| 17 h | 2 h | 0000 h | Alternate OEM Command Set (00h = none exists) |
| 18 h | 30 h | 0000 h |  |
| 19 h | 32 h | 0000 h | Address for Alternate OEM Extended Table (00h = none |
| 1 hh | 34 h | 0000 h | exists) |

Table 9.2 System Interface String

| Addresses (x16) | Addresses (x8) | Data | Description |
| :---: | :---: | :---: | :---: |
| 1Bh | 36h | 0027h | $\mathrm{V}_{\mathrm{CC}}$ Min. (write/erase) <br> D7-D4: volt, D3-D0: 100 millivolt |
| 1Ch | 38h | 0036h | V ${ }_{\text {CC }}$ Max. (write/erase) <br> D7-D4: volt, D3-D0: 100 millivolt |
| 1Dh | 3Ah | 0000h | $\mathrm{V}_{\mathrm{PP}}$ Min. voltage ( $00 \mathrm{~h}=$ no $\mathrm{V}_{\mathrm{PP}}$ pin present) |
| 1Eh | 3Ch | 0000h | $\mathrm{V}_{\mathrm{PP}}$ Max. voltage ( $00 \mathrm{~h}=$ no $\mathrm{V}_{\mathrm{PP}}$ pin present) |
| 1Fh | 3Eh | 0007h | Reserved for future use |
| 20h | 40h | 0007h | Typical timeout for Min. size buffer write $2^{\mathrm{N}} \mu \mathrm{s}$ (OOh = not supported) |
| 21h | 42h | 000Ah | Typical timeout per individual block erase $2^{\mathrm{N}} \mathrm{ms}$ |
| 22h | 44h | 0000h | Typical timeout for full chip erase $2^{\mathrm{N}} \mathrm{ms}$ (00h $=$ not supported) |
| 23h | 46h | 0003h | Max. timeout for byte/word program $2^{N}$ times typical. |
| 24h | 48h | 0005h | Max. timeout for buffer write $2^{\mathrm{N}}$ times typical |
| 25h | 4Ah | 0004h | Max. timeout per individual block erase $2^{N}$ times typical |
| 26h | 4Ch | 0000h | Max. timeout for full chip erase $2^{\mathrm{N}}$ times typical (00h = not supported) |

Note
CFI data related to $V_{C C}$ and time-outs may differ from actual $V_{C C}$ and time-outs of the product. Please consult the Ordering Information tables to obtain the $V_{C C}$ range for particular part numbers. Please consult the Erase and Programming Performance table for typical timeout specifications.

## 10. Command Definitions

Writing specific address and data commands or sequences into the command register initiates device operations. Table 10.1 on page 51 and Table 10.3 on page 53 define the valid register command sequences. Writing incorrect address and data values or writing them in the improper sequence may place the device in an unknown state. A reset command is then required to return the device to reading array data.

All addresses are latched on the falling edge of WE\# or CE\#, whichever happens later. All data is latched on the rising edge of WE\# or CE\#, whichever happens first. Refer to the AC Characteristics section for timing diagrams.

### 10.1 Reading Array Data

The device is automatically set to reading array data after device power-up. No commands are required to retrieve data. The device is ready to read array data after completing an Embedded Program or Embedded Erase algorithm.

After the device accepts an Erase Suspend command, the device enters the erase-suspend-read mode, after which the system can read data from any non-erase-suspended sector. After completing a programming operation in the Erase Suspend mode, the system may once again read array data with the same exception. See Erase Suspend/Erase Resume Commands on page 50 for more information.

The system must issue the reset command to return the device to the read (or erase-suspend-read) mode if DQ5 goes high during an active program or erase operation, or if the device is in the autoselect mode. See the next section, Reset Command, for more information.

See also Requirements for Reading Array Data in the Device Bus Operations section for more information. The Read-Only Operations-AC Characteristics on page 64 provide the read parameters, and Figure 15.2 on page 65 shows the timing diagram.

### 10.2 Reset Command

Writing the reset command resets the device to the read or erase-suspend-read mode. Address bits are don't cares for this command.

The reset command may be written between the sequence cycles in an erase command sequence before erasing begins. This resets the device to the read mode. Once erasure begins, however, the device ignores reset commands until the operation is complete.
The reset command may be written between the sequence cycles in a program command sequence before programming begins. This resets the device to the read mode. If the program command sequence is written while the device is in the Erase Suspend mode, writing the reset command returns the device to the erase-suspend-read mode. Once programming begins, however, the device ignores reset commands until the operation is complete.

The reset command may be written between the sequence cycles in an autoselect command sequence. Once in the autoselect mode, the reset command must be written to return to the read mode. If the device entered the autoselect mode while in the Erase Suspend mode, writing the reset command returns the device to the erase-suspend-read mode.

If DQ5 goes high during a program or erase operation, writing the reset command returns the device to the read mode (or erase-suspend-read mode if the device was in Erase Suspend).

Note that if DQ1 goes high during a Write Buffer Programming operation, the system must write the Write-to-Buffer-Abort Reset command sequence to reset the device for the next operation.

### 10.3 Autoselect Command Sequence

The autoselect command sequence allows the host system to read several identifier codes at specific addresses:

| Identifier Code | A7:A0 <br> (x16) | A6:A-1 <br> (x8) |
| :---: | :---: | :---: |
| Manufacturer ID | 00 h | 00 h |
| Device ID, Cycle 1 | 01 h | 02 h |
| Device ID, Cycle 2 | 0 Eh | 1 Ch |
| Device ID, Cycle 3 | 0Fh | 1Eh |
| Secured Silicon Sector Factory Protect | 03 h | 06 h |
| Sector Protect Verify | (SA)02h | (SA)04h |

Note
The device ID is read over three cycles. SA = Sector Address
The autoselect command sequence is initiated by first writing on unlock cycle (two cycles). This is followed by a third write cycle that contains the autoselect command. The device then enters the autoselect mode. The system may read at any address any number of times without initiating another autoselect command sequence:
The system must write the reset command to return to the read mode (or erase-suspend-read mode if the device was previously in Erase Suspend).

### 10.4 Enter/Exit Secured Silicon Sector Command Sequence

The Secured Silicon Sector region provides a secured data area containing an 8-word/16-byte random Electronic Serial Number (ESN). The system can access the Secured Silicon Sector region by issuing the three-cycle Enter Secured Silicon Sector command sequence. The device continues to access the Secured Silicon Sector region until the system issues the four-cycle Exit Secured Silicon Sector command sequence. The Exit Secured Silicon Sector command sequence returns the device to normal operation. Table 10.1 on page 51 and Table 10.3 on page 53 show the address and data requirements for both command sequences. See also Secured Silicon Sector Flash Memory Region on page 35 for further information. Note that the ACC function and unlock bypass modes are not available when the Secured Silicon Sector is enabled.

### 10.4.1 Word Program Command Sequence

Programming is a four-bus-cycle operation. The program command sequence is initiated by writing two unlock write cycles, followed by the program set-up command. The program address and data are written next, which in turn initiate the Embedded Program algorithm. The system is not required to provide further controls or timings. The device automatically provides internally generated program pulses and verifies the programmed cell margin. Table 10.1 on page 51 and Table 10.3 on page 53 show the address and data requirements for the word program command sequence, respectively.

When the Embedded Program algorithm is complete, the device then returns to the read mode and addresses are no longer latched. The system can determine the status of the program operation by using DQ7 or DQ6. Refer to the Write Operation Status section for information on these status bits. Any commands written to the device during the Embedded Program Algorithm are ignored. Note that the Secured Silicon Sector, autoselect, and CFI functions are unavailable when a program operation is in progress. Note that a hardware reset immediately terminates the program operation. The program command sequence should be reinitiated once the device returns to the read mode, to ensure data integrity.
Programming is allowed in any sequence of address locations and across sector boundaries. Programming to the same word address multiple times without intervening erases (incremental bit programming) requires a modified programming method. For such application requirements, please contact your local Spansion representative. Word programming is supported for backward compatibility with existing Flash driver software and for occasional writing of individual words. Use of write buffer programming (see below) is strongly recommended for general programming use when more than a few words are to be programmed. The effective word programming time using write buffer programming is approximately four times shorter than the single word programming time.

Any bit in a word cannot be programmed from $O$ back to a 1. Attempting to do so may cause the device to set DQ5=1, or cause DQ7 and DQ6 status bits to indicate the operation was successful. However, a succeeding read shows that the data is still 0 . Only erase operations can convert a 0 to a 1.

### 10.4.2 Unlock Bypass Command Sequence

The unlock bypass feature allows the system to program words to the device faster than using the standard program command sequence. The unlock bypass command sequence is initiated by first writing two unlock cycles. This is followed by a third write cycle containing the unlock bypass command, 20 h . The device then enters the unlock bypass mode. A two-cycle unlock bypass mode command sequence is all that is required to program in this mode. The first cycle in this sequence contains the unlock bypass program command, A0h; the second cycle contains the program address and data. Additional data is programmed in the same manner. This mode dispenses with the initial two unlock cycles required in the standard program command sequence, resulting in faster total programming time. Table 10.1 on page 51 and Table 10.3 on page 53 show the requirements for the command sequence.

During the unlock bypass mode, only the Unlock Bypass Program and Unlock Bypass Reset commands are valid. To exit the unlock bypass mode, the system must issue the two-cycle unlock bypass reset command sequence. The first cycle must contain the data 90h. The second cycle must contain the data 00h. The device then returns to the read mode.

### 10.4.3 Write Buffer Programming

Write Buffer Programming allows the system write to a maximum of 16 words/32 bytes in one programming operation. This results in faster effective programming time than the standard programming algorithms. The Write Buffer Programming command sequence is initiated by first writing two unlock cycles. This is followed by a third write cycle containing the Write Buffer Load command written at the Sector Address in which programming occurs. The fourth cycle writes the sector address and the number of word locations, minus one, to be programmed. For example, if the system programs six unique address locations, then 05h should be written to the device. This tells the device how many write buffer addresses are loaded with data and therefore when to expect the Program Buffer to Flash command. The number of locations to program cannot exceed the size of the write buffer or the operation aborts.
The fifth cycle writes the first address location and data to be programmed. The write-buffer-page is selected by address bits $\mathrm{A}_{\mathrm{MAX}}-\mathrm{A}_{4}$. All subsequent address/data pairs must fall within the selected-write-buffer-page. The system then writes the remaining address/data pairs into the write buffer. Write buffer locations may be loaded in any order.
The write-buffer-page address must be the same for all address/data pairs loaded into the write buffer. (This means Write Buffer Programming cannot be performed across multiple write-buffer pages.) This also means that Write Buffer Programming cannot be performed across multiple sectors. If the system attempts to load programming data outside of the selected write-buffer page, the operation aborts.

Note that if a Write Buffer address location is loaded multiple times, the address/data pair counter is decremented for every data load operation. The host system must therefore account for loading a write-buffer location more than once. The counter decrements for each data load operation, not for each unique write-buffer-address location. Note also that if an address location is loaded more than once into the buffer, the final data loaded for that address is programmed.

Once the specified number of write buffer locations are loaded, the system must then write the Program Buffer to Flash command at the sector address. Any other address and data combination aborts the Write Buffer Programming operation. The device then begins programming. Data polling should be used while monitoring the last address location loaded into the write buffer. DQ7, DQ6, DQ5, and DQ1 should be monitored to determine the device status during Write Buffer Programming.
The write-buffer programming operation can be suspended using the standard program suspend/resume commands. Upon successful completion of the Write Buffer Programming operation, the device is ready to execute the next command.

The Write Buffer Programming Sequence can be aborted in the following ways:
■ Load a value that is greater than the page buffer size during the Number of Locations to Program step.
■ Write to an address in a sector different than the one specified during the Write-Buffer-Load command.

■ Write an Address/Data pair to a different write-buffer-page than the one selected by the Starting Address during the write buffer data loading stage of the operation.

- Write data other than the Confirm Command after the specified number of data load cycles.

The abort condition is indicated by DQ1 = 1, DQ7 = DATA\# (for the last address location loaded), DQ6 = toggle, and DQ5 = 0 . A Write-to-Buffer-Abort Reset command sequence must be written to reset the device for the next operation.
Note that the Secured Silicon Sector, autoselect, and CFI functions are unavailable when a program operation is in progress. This flash device is capable of handling multiple write buffer programming operations on the same write buffer address range without intervening erases. For applications requiring incremental bit programming, a modified programming method is required; please contact your local Spansion representative. Any bit in a write buffer address range cannot be programmed from 0 back to a 1. Attempting to do so may cause the device to set DQ5=1, of cause the DQ7 and DQ6 status bits to indicate the operation was successful. However, a succeeding read shows that the data is still 0 . Only erase operations can convert a 0 to a 1.

### 10.4.4 Accelerated Program

The device offers accelerated program operations through the WP\#/ACC or ACC pin depending on the particular product. When the system asserts $\mathrm{V}_{\mathrm{HH}}$ on the WP\#/ACC or ACC pin. The device uses the higher voltage on the WP\#/ACC or ACC pin to accelerate the operation. Note that the WP\#/ACC pin must not be at $V_{H H}$ for operations other than accelerated programming, or device damage may result. WP\# contains an internal pull-up; when unconnected, WP\# is at $V_{I H}$.
Figure 10.1 on page 45 illustrates the algorithm for the program operation. Refer to the Erase and Program Operations-AC Characteristics on page 64 for parameters, and Figure 15.3 on page 65 for timing diagrams.

Figure 10.1 Write Buffer Programming Operation

## Notes

1. When Sector Address is specified, any address in the selected sector is acceptable. However, when loading Write-Buffer address locations with data, all addresses must fall within the selected Write-Buffer Page.
2. DQ7 may change simultaneously with DQ5. Therefore, DQ7 should be verified.
3. If this flowchart location was reached because $D Q 5=1$, then the device FAILED. If this flowchart location was reached because DQ1 $=1$, then the Write to Buffer operation was ABORTED. In either case, the proper reset command must be written before the device can begin another operation. If DQ1=1, write the Write-Buffer-Programming-Abort-Reset command. if DQ5=1, write the Reset command.
4. See Table 10.1 on page 51 and Table 10.3 on page 53 for command sequences required for write buffer programming.

Figure 10.2 Program Operation

Note
See Table 10.1 on page 51 and Table 10.3 on page 53 for program command sequence.

### 10.5 Program Suspend/Program Resume Command Sequence

The Program Suspend command allows the system to interrupt a programming operation or a Write to Buffer programming operation so that data can be read from any non-suspended sector. When the Program Suspend command is written during a programming process, the device halts the program operation within $20 \mu \mathrm{~s}$ maximum and updates the status bits. Addresses are not required when writing the Program Suspend command.
After the programming operation is suspended, the system can read array data from any non-suspended sector. The Program Suspend command may also be issued during a programming operation while an erase is suspended. In this case, data may be read from any addresses not in Erase Suspend or Program Suspend. If a read is needed from the Secured Silicon Sector area (One-time Program area), then user must use the proper command sequences to enter and exit this region. Note that the Secured Silicon Sector, autoselect, and CFI functions are unavailable when a program operation is in progress.
The system may also write the autoselect command sequence when the device is in the Program Suspend mode. The system can read as many autoselect codes as required. When the device exits the autoselect mode, the device reverts to the Program Suspend mode, and is ready for another valid operation. See Autoselect Command Sequence on page 42 for more information.
After the Program Resume command is written, the device reverts to programming. The system can determine the status of the program operation using the DQ7 or DQ6 status bits, just as in the standard program operation. See Write Operation Status on page 55 for more information.
The system must write the Program Resume command (address bits are don't care) to exit the Program Suspend mode and continue the programming operation. Further writes of the Resume command are ignored. Another Program Suspend command can be written after the device resumes programming.

Figure 10.3 Program Suspend/Program Resume

### 10.6 Chip Erase Command Sequence

Chip erase is a six bus cycle operation. The chip erase command sequence is initiated by writing two unlock cycles, followed by a set-up command. Two additional unlock write cycles are then followed by the chip erase command, which in turn invokes the Embedded Erase algorithm. The device does not require the system to preprogram prior to erase. The Embedded Erase algorithm automatically preprograms and verifies the entire memory for an all zero data pattern prior to electrical erase. The system is not required to provide any controls or timings during these operations. Table 10.1 on page 51 and Table 10.3 on page 53 show the address and data requirements for the chip erase command sequence.
When the Embedded Erase algorithm is complete, the device returns to the read mode and addresses are no longer latched. The system can determine the status of the erase operation by using DQ7, DQ6, or DQ2. Refer to Write Operation Status on page 55 for information on these status bits.
Any commands written during the chip erase operation are ignored. However, note that a hardware reset immediately terminates the erase operation. If this occurs, the chip erase command sequence should be reinitiated once the device returns to reading array data, to ensure data integrity.

Figure 10.4 on page 49 illustrates the algorithm for the erase operation. Refer to Table 15.3 on page 67 for parameters, and Figure 15.7 on page 69 for timing diagrams.

### 10.7 Sector Erase Command Sequence

Sector erase is a six bus cycle operation. The sector erase command sequence is initiated by writing two unlock cycles, followed by a set-up command. Two additional unlock cycles are written, and are then followed by the address of the sector to be erased, and the sector erase command. Table 10.1 on page 51 and Table 10.3 on page 53 shows the address and data requirements for the sector erase command sequence.
The device does not require the system to preprogram prior to erase. The Embedded Erase algorithm automatically programs and verifies the entire memory for an all zero data pattern prior to electrical erase. The system is not required to provide any controls or timings during these operations.

After the command sequence is written, a sector erase time-out of $50 \mu \mathrm{~s}$ occurs. During the time-out period, additional sector addresses and sector erase commands may be written. Loading the sector erase buffer may be done in any sequence, and the number of sectors may be from one sector to all sectors. The time between these additional cycles must be less than $50 \mu \mathrm{~s}$, otherwise erasure may begin. Any sector erase address and command following the exceeded time-out may or may not be accepted. It is recommended that processor interrupts be disabled during this time to ensure all commands are accepted. The interrupts can be re-enabled after the last Sector Erase command is written. Any command other than Sector Erase or Erase Suspend during the time-out period resets the device to the read mode. Note that the Secured Silicon Sector, autoselect, and CFI functions are unavailable when an erase operation is in progress. The system must rewrite the command sequence and any additional addresses and commands.
The system can monitor DQ3 to determine if the sector erase timer has timed out (See the section on DQ3: Sector Erase Timer.). The time-out begins from the rising edge of the final WE\# pulse in the command sequence.
When the Embedded Erase algorithm is complete, the device returns to reading array data and addresses are no longer latched. The system can determine the status of the erase operation by reading DQ7, DQ6, or DQ2 in the erasing sector. Refer to the Write Operation Status section for information on these status bits.
Once the sector erase operation begins, only the Erase Suspend command is valid. All other commands are ignored. However, note that a hardware reset immediately terminates the erase operation. If that occurs, the sector erase command sequence should be reinitiated once the device returns to reading array data, to ensure data integrity.
Figure 10.4 on page 49 illustrates the algorithm for the erase operation. Refer to Table 15.3 on page 67 for parameters, and Figure 15.7 on page 69 for timing diagrams.

Figure 10.4 Erase Operation

[^0]
### 10.8 Erase Suspend/Erase Resume Commands

The Erase Suspend command, B0h, allows the system to interrupt a sector erase operation and then read data from, or program data to, any sector not selected for erasure. This command is valid only during the sector erase operation, including the $50 \mu$ s time-out period during the sector erase command sequence. The Erase Suspend command is ignored if written during the chip erase operation or Embedded Program algorithm.
When the Erase Suspend command is written during the sector erase operation, the device requires a typical of $5 \mu \mathrm{~s}$ (maximum of $20 \mu \mathrm{~s}$ ) to suspend the erase operation. However, when the Erase Suspend command is written during the sector erase time-out, the device immediately terminates the time-out period and suspends the erase operation.
After the erase operation is suspended, the device enters the erase-suspend-read mode. The system can read data from or program data to any sector not selected for erasure. (The device erase suspends all sectors selected for erasure.) Reading at any address within erase-suspended sectors produces status information on DQ7-DQ0. The system can use DQ7, or DQ6 and DQ2 together, to determine if a sector is actively erasing or is erase-suspended. Refer to Write Operation Status on page 55 for information on these status bits.

After an erase-suspended program operation is complete, the device returns to the erase-suspend-read mode. The system can determine the status of the program operation using the DQ7 or DQ6 status bits, just as in the standard word program operation. Refer to Write Operation Status on page 55 for more information.
In the erase-suspend-read mode, the system can also issue the autoselect command sequence. Refer to the Autoselect Mode on page 29 and Autoselect Command Sequence on page 42 sections for details.
To resume the sector erase operation, the system must write the Erase Resume command. Further writes of the Resume command are ignored. Another Erase Suspend command can be written after the chip resumes erasing.
During an erase operation, this flash device performs multiple internal operations which are invisible to the system. When an erase operation is suspended, any of the internal operations that were not fully completed must be restarted. As such, if this flash device is continually issued suspend/resume commands in rapid succession, erase progress is impeded as a function of the number of suspends. The result is a longer cumulative erase time than without suspends. Note that the additional suspends do not affect device reliability or future performance. In most systems rapid erase/suspend activity occurs only briefly. In such cases, erase performance is not significantly impacted.

### 10.9 Command Definitions

Table 10.1 Command Definitions ( $x 16$ Mode, BYTE\# $=V_{I H}$ )

| Command <br> Sequence (Note 1) | $\begin{aligned} & \text { y } \\ & \frac{0}{0} \\ & 0 \end{aligned}$ | Bus Cycles (Notes 2-5) |  |  |  |  |  |  |  |  |  |  |  |

## Legend

## X = Don't care

$R A=$ Read Address of memory location to be read.
$R D=$ Read Data read from location RA during read operation.
PA = Program Address. Addresses latch on falling edge of WE\# or CE\# pulse, whichever happens later.

## Notes

1. See Table 8.1 on page 17 for description of bus operations.
2. All values are in hexadecimal.
3. Shaded cells indicate read cycles. All others are write cycles.
4. During unlock and command cycles, when lower address bits are 555 or $2 A A$ as shown in table, address bits above A11 and data bits above DQ7 are don't care.
5. No unlock or command cycles required when device is in read mode.
6. Reset command is required to return to read mode (or to erase-suspendread mode if previously in Erase Suspend) when device is in autoselect mode, or if DQ5 goes high while device is providing status information.
7. Fourth cycle of the autoselect command sequence is a read cycle. Data bits DQ15-DQ8 are don't care. Except for RD, PD and WC. See Autoselect Command Sequence on page 42 for more information.
8. For S29GL064N and S29GL032N, Device ID must be read in three cycles.
9. Refer to Table 8.9 on page 29 for data indicating Secured Silicon Sector factory protect status.
10. Data is 00 h for an unprotected sector and 01 h for a protected sector.
$P D=$ Program Data for location PA. Data latches on rising edge of WE\# or
CE\# pulse, whichever happens first.
SA = Sector Address of sector to be verified (in autoselect mode) or erased. Address bits A21-A15 uniquely select any sector.
WBL $=$ Write Buffer Location. Address must be within same write buffer page as PA.
WC $=$ Word Count. Number of write buffer locations to load minus 1.
11. Total number of cycles in command sequence is determined by number of words written to write buffer. Maximum number of cycles in command sequence is 21, including Program Buffer to Flash command.
12. Command sequence resets device for next command after aborted write-to-buffer operation.
13. Unlock Bypass command is required prior to Unlock Bypass Program command.
14. Unlock Bypass Reset command is required to return to read mode when device is in unlock bypass mode.
15. System may read and program in non-erasing sectors, or enter autoselect mode, when in Erase Suspend mode. Erase Suspend command is valid only during a sector erase operation.
16. Erase Resume command is valid only during Erase Suspend mode.
17. Command is valid when device is ready to read array data or when device is in autoselect mode.
18. Refer to Table 8.9 on page 29, for individual Device IDs per device density and model number.

Table 10.2 Sector Protection Commands (x16)

| Command Sequence (Notes) |  | $\begin{aligned} & \boldsymbol{y} \\ & \frac{\mathbf{0}}{0} \\ & \underset{\sim}{u} \end{aligned}$ | Bus Cycles (Notes 2-4) |  |  |  |  |  |  |  |  |  |  |  |  |  |

## Legend

$X=$ Don't care.
$R A=$ Address of the memory location to be read.
SA = Sector Address. Any address that falls within a specified sector. See Tables 8.2-8.8 for sector address ranges.

## Notes

1. All values are in hexadecimal.
2. Shaded cells indicate read cycles.
3. Address and data bits not specified in table, legend, or notes are don't cares (each hex digit implies 4 bits of data).
4. Writing incorrect address and data values or writing them in the improper sequence may place the device in an unknown state. The system must write the reset command to return the device to reading array data.
5. Entry commands are required to enter a specific mode to enable instructions only available within that mode.
6. No unlock or command cycles required when bank is reading array data.

PWA = Password Address. Address bits A1 and A0 are used to select each 16bit portion of the 64-bit entity.
PWD = Password Data.
$R D(0)=D Q 0$ protection indicator bit. If protected, $D Q O=0$. If unprotected,
$D Q O=1$.
7. Exit command must be issued to reset the device into read mode; device may otherwise be placed in an unknown state.
8. Entire two bus-cycle sequence must be entered for each portion of the password.
9. Full address range is required for reading password.
10. Password may be unlocked or read in any order. Unlocking requires the full password (all seven cycles).
11. ACC must be at $V_{I H}$ when setting PPB or DYB.
12. "All PPB Erase" command pre-programs all PPBs before erasure to prevent over-erasure.

Table 10.3 Command Definitions ( x 8 Mode, BYTE\# $=\mathrm{V}_{\mathrm{IL}}$ )

Legend
X = Don't care
$R A=$ Read Address of memory location to be read.
$R D=$ Read Data read from location RA during read operation.
PA = Program Address. Addresses latch on falling edge of WE\# or CE\# pulse, whichever happens later.

## Notes

1. See Table 8.1 on page 17 for description of bus operations.
2. All values are in hexadecimal.
3. Shaded cells indicate read cycles. All others are write cycles.
4. During unlock and command cycles, when lower address bits are 555 or AAA as shown in table, address bits above A11 are don't care.
5. Unless otherwise noted, address bits A21-A11 are don't cares.
6. No unlock or command cycles required when device is in read mode.
7. Reset command is required to return to read mode (or to erase-suspendread mode if previously in Erase Suspend) when device is in autoselect mode, or if DQ5 goes high while device is providing status information.
8. Fourth cycle of autoselect command sequence is a read cycle. Data bits DQ15-DQ8 are don't care. See Autoselect Command Sequence on page 42 for more information.
9. For S29GL064N and S29GL032A Device ID must be read in three cycles.
$P D=$ Program Data for location PA. Data latches on rising edge of WE\# or CE\# pulse, whichever happens first.
SA = Sector Address of sector to be verified (in autoselect mode) or erased. Address bits A21-A15 uniquely select any sector.
WBL $=$ Write Buffer Location. Address must be within same write buffer page as PA.
$B C=$ Byte Count. Number of write buffer locations to load minus 1.
10. Refer to Table 8.9 on page 29, for data indicating Secured Silicon Sector factory protect status.
11. Data is 00 h for an unprotected sector and 01 h for a protected sector.
12. Total number of cycles in command sequence is determined by number of bytes written to write buffer. Maximum number of cycles in command sequence is 37, including Program Buffer to Flash command.
13. Command sequence resets device for next command after aborted write-to-buffer operation.
14. System may read and program in non-erasing sectors, or enter autoselect mode, when in Erase Suspend mode. Erase Suspend command is valid only during a sector erase operation.
15. Erase Resume command is valid only during Erase Suspend mode.
16. Command is valid when device is ready to read array data or when device is in autoselect mode.
17. Refer to Table 8.9 on page 29, for individual Device IDs per device density and model number.

Table 10.4 Sector Protection Commands (x8)

| Command Sequence (Notes) |  | $$ | Bus Cycles (Notes 2-5) |  |  |  |  |  |  |  |  |  |  |  |  |  |

## Legend

$X=$ Don't care.
$R A=$ Address of the memory location to be read.
SA = Sector Address. Any address that falls within a specified sector. See Tables 8.2-8.8 for sector address ranges.

## Notes

1. All values are in hexadecimal.
2. Shaded cells indicate read cycles.
3. Address and data bits not specified in table, legend, or notes are don't cares (each hex digit implies 4 bits of data).
4. Writing incorrect address and data values or writing them in the improper sequence may place the device in an unknown state. The system must write the reset command to return the device to reading array data.
5. Entry commands are required to enter a specific mode to enable instructions only available within that mode.
6. No unlock or command cycles required when bank is reading array data.

PWA = Password Address. Address bits A1 and A0 are used to select each 16bit portion of the 64-bit entity.
PWD = Password Data.
$R D(0)=D Q 0$ protection indicator bit. If protected, $D Q O=0$. If unprotected, $D Q O=1$.
7. Exit command must be issued to reset the device into read mode; device may otherwise be placed in an unknown state.
8. Entire two bus-cycle sequence must be entered for each portion of the password.
9. Full address range is required for reading password.
10. Password may be unlocked or read in any order. Unlocking requires the full password (all seven cycles).
11. ACC must be at $V_{I H}$ when setting $P P B$ or DYB.
12. "All PPB Erase" command pre-programs all PPBs before erasure to prevent over-erasure.

### 10.10 Write Operation Status

The device provides several bits to determine the status of a program or erase operation: DQ2, DQ3, DQ5, DQ6, and DQ7. Table 10.5 on page 60 and the following subsections describe the function of these bits. DQ7 and DQ6 each offer a method for determining whether a program or erase operation is complete or in progress. The device also provides a hardware-based output signal, RY/BY\#, to determine whether an Embedded Program or Erase operation is in progress or is completed.

### 10.11 DQ7: Data\# Polling

The Data\# Polling bit, DQ7, indicates to the host system whether an Embedded Program or Erase algorithm is in progress or completed, or whether the device is in Erase Suspend. Data\# Polling is valid after the rising edge of the final WE\# pulse in the command sequence.
During the Embedded Program algorithm, the device outputs on DQ7 the complement of the datum programmed to DQ7. This DQ7 status also applies to programming during Erase Suspend. When the Embedded Program algorithm is complete, the device outputs the datum programmed to DQ7. The system must provide the program address to read valid status information on DQ7. If a program address falls within a protected sector, Data\# Polling on DQ7 is active for approximately $1 \mu \mathrm{~s}$, then the device returns to the read mode.

During the Embedded Erase algorithm, Data\# Polling produces a 0 on DQ7. When the Embedded Erase algorithm is complete, or if the device enters the Erase Suspend mode, Data\# Polling produces a 1 on DQ7. The system must provide an address within any of the sectors selected for erasure to read valid status information on DQ7.

After an erase command sequence is written, if all sectors selected for erasing are protected, Data\# Polling on DQ7 is active for approximately $100 \mu \mathrm{~s}$, then the device returns to the read mode. If not all selected sectors are protected, the Embedded Erase algorithm erases the unprotected sectors, and ignores the selected sectors that are protected. However, if the system reads DQ7 at an address within a protected sector, the status may not be valid.
Just prior to the completion of an Embedded Program or Erase operation, DQ7 may change asynchronously with DQ0-DQ6 while Output Enable (OE\#) is asserted low. That is, the device may change from providing status information to valid data on DQ7. Depending on when the system samples the DQ7 output, it may read the status or valid data. Even if the device completed the program or erase operation and DQ7 has valid data, the data outputs on DQ0-DQ6 may be still invalid. Valid data on DQ0-DQ7 appears on successive read cycles.

Table 10.5 on page 60 shows the outputs for Data\# Polling on DQ7. Figure 10.5 on page 56 shows the Data\# Polling algorithm. Figure 15.8 on page 69 shows the Data\# Polling timing diagram.

Figure 10.5 Data\# Polling Algorithm

Notes

1. $V A=$ Valid address for programming. During a sector erase operation, a valid address is any sector address within the sector being erased. During chip erase, a valid address is any non-protected sector address.
2. DQ7 should be rechecked even if $D Q 5=1$ because DQ7 may change simultaneously with DQ5.

### 10.12 RY/BY\#: Ready/Busy\#

The RY/BY\# is a dedicated, open-drain output pin which indicates whether an Embedded Algorithm is in progress or complete. The RY/BY\# status is valid after the rising edge of the final WE\# pulse in the command sequence. Since RY/BY\# is an open-drain output, several RY/BY\# pins can be tied together in parallel with a pull-up resistor to $\mathrm{V}_{\mathrm{CC}}$.
If the output is low (Busy), the device is actively erasing or programming. (This includes programming in the Erase Suspend mode.) If the output is high (Ready), the device is in the read mode, the standby mode, or in the erase-suspend-read mode. Table 10.5 on page 60 shows the outputs for RY/BY\#.

### 10.13 DQ6: Toggle Bit I

Toggle Bit I on DQ6 indicates whether an Embedded Program or Erase algorithm is in progress or complete, or whether the device entered the Erase Suspend mode. Toggle Bit I may be read at any address, and is valid after the rising edge of the final WE\# pulse in the command sequence (prior to the program or erase operation), and during the sector erase time-out.

During an Embedded Program or Erase algorithm operation, successive read cycles to any address cause DQ6 to toggle. The system may use either OE\# or CE\# to control the read cycles. When the operation is complete, DQ6 stops toggling.
After an erase command sequence is written, if all sectors selected for erasing are protected, DQ6 toggles for approximately $100 \mu \mathrm{~s}$, then returns to reading array data. If not all selected sectors are protected, the Embedded Erase algorithm erases the unprotected sectors, and ignores the selected sectors that are protected.

The system can use DQ6 and DQ2 together to determine whether a sector is actively erasing or is erasesuspended. When the device is actively erasing (that is, the Embedded Erase algorithm is in progress), DQ6 toggles. When the device enters the Erase Suspend mode, DQ6 stops toggling. However, the system must also use DQ2 to determine which sectors are erasing or erase-suspended. Alternatively, the system can use DQ7 (see DQ7: Data\# Polling on page 55).
If a program address falls within a protected sector, DQ6 toggles for approximately $1 \mu \mathrm{~s}$ after the program command sequence is written, then returns to reading array data.
DQ6 also toggles during the erase-suspend-program mode, and stops toggling once the Embedded Program algorithm is complete.
Table 10.5 on page 60 shows the outputs for Toggle Bit I on DQ6. Figure 10.6 on page 58 shows the toggle bit algorithm. Figure 15.9 on page 70 shows the toggle bit timing diagrams. Figure 15.10 on page 70 shows the differences between DQ2 and DQ6 in graphical form. See also the subsection on DQ2: Toggle Bit II on page 58.

Figure 10.6 Toggle Bit Algorithm

Note
The system should recheck the toggle bit even if DQ5 = 1 because the toggle bit may stop toggling as DQ5 changes to 1 . See the subsections on DQ6 and DQ2 for more information.

### 10.14 DQ2: Toggle Bit II

The "Toggle Bit II" on DQ2, when used with DQ6, indicates whether a particular sector is actively erasing (that is, the Embedded Erase algorithm is in progress), or whether that sector is erase-suspended. Toggle Bit II is valid after the rising edge of the final WE\# pulse in the command sequence.

DQ2 toggles when the system reads at addresses within those sectors that were selected for erasure. (The system may use either OE\# or CE\# to control the read cycles.) But DQ2 cannot distinguish whether the sector is actively erasing or is erase-suspended. DQ6, by comparison, indicates whether the device is actively erasing, or is in Erase Suspend, but cannot distinguish which sectors are selected for erasure. Thus, both status bits are required for sector and mode information. Refer to Table 10.5 on page 60 to compare outputs for DQ2 and DQ6.

Figure 10.6 on page 58 shows the toggle bit algorithm in flowchart form. Figure 15.9 on page 70 shows the toggle bit timing diagram. Figure 15.10 on page 70 shows the differences between DQ2 and DQ6 in graphical form.

### 10.15 Reading Toggle Bits DQ6/DQ2

Refer to Figure 10.6 on page 58 for the following discussion. Whenever the system initially begins reading toggle bit status, it must read DQ7-DQ0 at least twice in a row to determine whether a toggle bit is toggling. Typically, the system would note and store the value of the toggle bit after the first read. After the second read, the system would compare the new value of the toggle bit with the first. If the toggle bit is not toggling, the device completed the program or erase operation. The system can read array data on DQ7-DQ0 on the following read cycle.

However, if after the initial two read cycles, the system determines that the toggle bit is still toggling, the system also should note whether the value of DQ5 is high (see the section on DQ5). If it is, the system should then determine again whether the toggle bit is toggling, since the toggle bit may have stopped toggling just as DQ5 went high. If the toggle bit is no longer toggling, the device successfully completed the program or erase operation. If it is still toggling, the device did not completed the operation successfully, and the system must write the reset command to return to reading array data.

The remaining scenario is that the system initially determines that the toggle bit is toggling and DQ5 has not gone high. The system may continue to monitor the toggle bit and DQ5 through successive read cycles, determining the status as described in the previous paragraph. Alternatively, it may choose to perform other system tasks. In this case, the system must start at the beginning of the algorithm when it returns to determine the status of the operation (top of Figure 10.6 on page 58).

### 10.16 DQ5: Exceeded Timing Limits

DQ5 indicates whether the program, erase, or write-to-buffer time exceeded a specified internal pulse count limit. Under these conditions DQ5 produces a 1. indicating that the program or erase cycle was not successfully completed.

The device may output a 1 on DQ5 if the system tries to program a 1 to a location that was previously programmed to 0 . Only an erase operation can change a $\mathbf{0}$ back to a 1 . Under this condition, the device halts the operation, and when the timing limit is exceeded, DQ5 produces a 1.

In all these cases, the system must write the reset command to return the device to the reading the array (or to erase-suspend-read if the device was previously in the erase-suspend-program mode).

### 10.17 DQ3: Sector Erase Timer

After writing a sector erase command sequence, the system may read DQ3 to determine whether or not erasure began. (The sector erase timer does not apply to the chip erase command.) If additional sectors are selected for erasure, the entire time-out also applies after each additional sector erase command. When the time-out period is complete, DQ3 switches from a 0 to a 1 . If the time between additional sector erase commands from the system can be assumed to be less than $50 \mu \mathrm{~s}$, the system need not monitor DQ3. See also the Sector Erase Command Sequence section.
After the sector erase command is written, the system should read the status of DQ7 (Data\# Polling) or DQ6 (Toggle Bit I) to ensure that the device accepted the command sequence, and then read DQ3. If DQ3 is 1, the Embedded Erase algorithm has begun; all further commands (except Erase Suspend) are ignored until the erase operation is complete. If DQ3 is 0 , the device accepts additional sector erase commands. To ensure the command is accepted, the system software should check the status of DQ3 prior to and following each subsequent sector erase command. If DQ3 is high on the second status check, the last command might not have been accepted.

Table 10.5 on page 60 shows the status of DQ3 relative to the other status bits.

### 10.18 DQ1: Write-to-Buffer Abort

DQ1 indicates whether a Write-to-Buffer operation was aborted. Under these conditions DQ1 produces a 1. The system must issue the Write-to-Buffer-Abort-Reset command sequence to return the device to reading array data. See Write Buffer on page 18 for more details.

Table 10.5 Write Operation Status

| Status |  |  | $\begin{gathered} \text { DQ7 } \\ \text { (Note 2) } \end{gathered}$ | DQ6 | $\begin{gathered} \text { DQ5 } \\ \text { (Note 1) } \end{gathered}$ | DQ3 | $\begin{aligned} & \text { DQ2 } \\ & \text { (Note 2) } \end{aligned}$ | DQ1 | RY/BY\# |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Standard Mode | Embedded Program Algorithm |  | DQ7\# | Toggle | 0 | N/A | No toggle | 0 | 0 |
|  | Embedded Erase Algorithm |  | 0 | Toggle | 0 | 1 | Toggle | N/A | 0 |
| Program Suspend Mode | ProgramSuspend Read | Program-Suspended Sector | Invalid (not allowed) |  |  |  |  |  | 1 |
|  |  | Non-Program Suspended Sector | Data |  |  |  |  |  | 1 |
| Erase Suspend Mode | Erase- <br> Suspend <br> Read | Erase-Suspended Sector | 1 | No toggle | 0 | N/A | Toggle | N/A | 1 |
|  |  | Non-Erase Suspended Sector | Data |  |  |  |  |  | 1 |
|  | Erase-Suspend-Program (Embedded Program) |  | DQ7\# | Toggle | 0 | N/A | N/A | N/A | 0 |
| Write-toBuffer | Busy (Note 3) |  | DQ7\# | Toggle | 0 | N/A | N/A | 0 | 0 |
|  | Abort (Note 4) |  | DQ7\# | Toggle | 0 | N/A | N/A | 1 | 0 |

## Notes

1. DQ5 switches to 1 when an Embedded Program, Embedded Erase, or Write-to-Buffer operation exceeded the maximum timing limits. Refer to the section on DQ5 for more information.
2. DQ7 and DQ2 require a valid address when reading status information. Refer to the appropriate subsection for further details.
3. The Data\# Polling algorithm should be used to monitor the last loaded write-buffer address location.
4. DQ1 switches to 1 when the device aborts the write-to-buffer operation.

## 11. Absolute Maximum Ratings

| Parameter |  | Rating |
| :--- | :--- | :--- |
| Storage Temperature, Plastic Packages | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |  |
| Ambient Temperature with Power Applied | $-65^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |  |
| Voltage with Respect to Ground | $\mathrm{V}_{\mathrm{CC}}$ (Note 1) | -0.5 V to +4.0 V |
|  | A9, ACC and RESET\# (Note 2) | -0.5 V to +12.5 V |
|  | All other pins (Note 1) | -0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$ |
| Output Short Circuit Current | (Note 3) | 200 mA |

Notes

1. Minimum DC voltage on input or I/Os is -0.5 V. During voltage transitions, inputs or I/Os may overshoot $V_{S S}$ to -2.0 V for periods of up to 20 ns . See Figure 11.1. Maximum DC voltage on input or I/Os is $V_{C C}+0.5 \mathrm{~V}$. During voltage transitions, input or I/O pins may overshoot to $V_{C C}+2.0 \mathrm{~V}$ for periods up to 20 ns . See Figure 11.2.
2. Minimum DC input voltage on pins A9, ACC, and RESET\# is -0.5 V. During voltage transitions, A9, ACC, and RESET\# may overshoot $V_{S S}$ to -2.0 V for periods of up to 20 ns . See Figure 11.1. Maximum DC input voltage on pin A9, ACC, and RESET\# is +12.5 V which may overshoot to +14.0 V for periods up to 20 ns .
3. No more than one output may be shorted to ground at a time. Duration of the short circuit should not be greater than one second.
4. Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational sections of this data sheet is not implied. Exposure of the device to absolute maximum rating conditions for extended periods may affect device reliability.

Figure 11.1 Maximum Negative Overshoot Waveform

Figure 11.2 Maximum Positive Overshoot Waveform

## 12. Operating Ranges

| Parameter |  | Range |
| :--- | :---: | :---: |
| Ambient Temperature $\left(\mathrm{T}_{\mathrm{A}}\right)$, Industrial (I) Devices | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |  |
| Supply Voltages | $\mathrm{V}_{\mathrm{CC}}$ for full voltage range | +2.7 V to +3.6 V |
|  | $\mathrm{~V}_{\mathrm{IO}}$ | +1.65 to +3.6 V |

[^1]
## 13. DC Characteristics

Table 13.1 DC Characteristics, CMOS Compatible

| Parameter Symbol | Parameter Description (Notes) | Test Conditions |  | Min | Typ | Max | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{I}_{\mathrm{LI}}$ | Input Load Current (Note 1) | $\begin{aligned} & V_{\text {IN }}=V_{S S} \text { to } V_{C C}, \\ & V_{C C}=V_{C C} \text { max } \end{aligned}$ |  |  |  | WP\#/ACC: $\pm 2.0 \mu \mathrm{~A}$ | $\mu \mathrm{A}$ |

| $\mathrm{I}_{\text {ACC }}$ | ACC Accelerated Program Current | $\begin{aligned} & C E \#=V_{I L}, O E \#=V_{I H}, \\ & V_{C C}=V_{C C} \text { max, } \\ & W P \# / A C C=V_{I H} \end{aligned}$ | $\begin{aligned} & \hline \text { WP\#/ } \\ & \text { ACC } \end{aligned}$ |  | 10 | 20 | mA |
|  |  |  | $\mathrm{V}_{\mathrm{CC}}$ |  | 50 | 60 | mA |
| $\mathrm{V}_{\text {IL }}$ | Input Low Voltage 1 (Note 5) |  |  | -0.1 |  | $0.3 \times \mathrm{V}_{\text {IO }}$ | V |
| $\mathrm{V}_{\mathrm{IH}}$ | Input High Voltage 1 (Note 5) |  |  | $0.7 \mathrm{~V}_{1 \mathrm{O}}$ |  | $\mathrm{V}_{1 \mathrm{O}}+0.3$ | V |
| $\mathrm{V}_{\mathrm{HH}}$ | Voltage for ACC Program Acceleration | $\mathrm{V}_{\mathrm{CC}}=2.7-3.6 \mathrm{~V}$ |  | 11.5 |  | 12.5 | V |
| $\mathrm{V}_{\text {ID }}$ | Voltage for Autoselect | $\mathrm{V}_{\mathrm{CC}}=2.7-3.6 \mathrm{~V}$ |  | 11.5 |  | 12.5 | V |
| $\mathrm{V}_{\mathrm{OL}}$ | Output Low Voltage (Note 5) | $\mathrm{I}_{\mathrm{OL}}=100 \mu \mathrm{~A}$ |  |  |  | $0.15 \times \mathrm{V}_{10}$ | V |
| $\mathrm{V}_{\mathrm{OH} 1}$ | Output High Voltage (Note 5) | $\mathrm{I}_{\mathrm{OH}}=-100 \mu \mathrm{~A}$ |  | $\begin{aligned} & 0.85 \\ & V_{10} \end{aligned}$ |  |  | V |
| $\mathrm{V}_{\mathrm{OH} 2}$ |  |  |  |  |  |  |  |
| $\mathrm{V}_{\text {LKO }}$ | Low $\mathrm{V}_{\text {CC }}$ Lock-Out Voltage (Note 3) |  |  |  | 2.3 |  | 2.5 | V |

## Notes

1. ICC current listed is typically less than $5.5 \mathrm{~mA} / \mathrm{MHz}$, with OE\# at $V_{I H}$.
2. ICC active while Embedded Erase, Embedded Program, or Write Buffer Programming is in progress.
3. Not $100 \%$ tested.
4. Automatic sleep mode enables the low power mode when addresses remain stable for $t_{A C C}+30 \mathrm{~ns}$.
5. $V_{I O}=1.65-1.95 \mathrm{~V}$ or $2.7-3.6 \mathrm{~V}$.
6. $V_{C C}=3 \mathrm{~V}$ and $V_{I O}=3 \mathrm{~V}$ or 1.8 V . When $V_{I O}$ is at 1.8 V , I/Os cannot operate at 3 V .

## 14. Test Conditions

Figure 14.1 Test Setup

Note
Diodes are IN3064 or equivalent.

Table 14.1 Test Specifications

| Test Condition | All Speeds | Unit |
| :--- | :---: | :---: |
| Output Load | 1 TTL gate |  |
| Output Load Capacitance, $\mathrm{C}_{\mathrm{L}}$ <br> (including jig capacitance) | 30 | pF |
| Input Rise and Fall Times | 5 | ns |
| Input Pulse Levels | 0.0 or $\mathrm{V}_{1 \mathrm{O}}$ | V |
| Input timing measurement reference levels | $0.5 \mathrm{~V}_{1 \mathrm{O}}$ | V |
| Output timing measurement reference levels | $0.5 \mathrm{~V}_{1 \mathrm{O}}$ | V |

### 14.1 Key to Switching Waveforms

| Waveform | Inputs | Outputs |
| :---: | :---: | :---: |

|  |  | Accelerated Single Word Program Operation (Note 2) | Typ | 54 |  |  |
| $\mathrm{t}_{\text {WHWH2 }}$ | $\mathrm{t}_{\text {WHWH2 }}$ | Sector Erase Operation (Note 2) | Typ | 0.5 |  | sec |
|  | $\mathrm{t}_{\mathrm{RH}}$ | RESET\# High Time Before Write | Min | 50 |  | ns |

## Notes

1. Not $100 \%$ tested.
2. See the Erase And Programming Performance on page 73 for more information.
3. For $1-16$ words/1-32 bytes programmed.

Figure 15.11 Alternate CE\# Controlled Write (Erase/Program) Operation Timings

## Notes

1. Figure indicates last two bus cycles of a program or erase operation.
2. $P A=$ program address, $S A=$ sector address, $P D=$ program data.
3. DQ7\# is the complement of the data written to the device. Dout is the data written to the device.
4. Illustration shows device in word mode.

## 16. Erase And Programming Performance

| Parameter |  | Typ (Note 1) | $\begin{gathered} \text { Max } \\ \text { (Note 2) } \end{gathered}$ | Unit | Comments |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Sector Erase Time |  | 0.5 | 3.5 | sec | Excludes 00h programming prior to erasure (Note 6) |
| Chip Erase Time | S29GL032N | 32 | 64 |  |  |
|  | S29GL064N | 64 | 128 |  |  |
| Total Write Buffer Program Time (Notes 3, 5) |  | 240 |  | $\mu \mathrm{s}$ | Excludes system level overhead (Note 7) |
| Total Accelerated Effective Write Buffer Program Time (Notes 4, 5) |  | 200 |  |  |  |
| Chip Program Time | S29GL032N | 31.5 |  | sec |  |
|  | S29GL064N | 63 |  |  |  |

## Notes

1. Typical program and erase times assume the following conditions: $25^{\circ} \mathrm{C}, V_{C C}=3.0 \mathrm{~V}, 10,000$ cycles; checkerboard data pattern.
2. Under worst case conditions of $90^{\circ} \mathrm{C}$; Worst case $V_{C C}, 100,000$ cycles.
3. Programming time (typ) is $15 \mu s$ (per word), $7.5 \mu \mathrm{~s}$ (per byte).
4. Accelerated programming time (typ) is $12.5 \mu s$ (per word), $6.3 \mu s$ (per byte).
5. Write buffer Programming time is calculated on a per-word/per-byte basis for a 16-word/32-byte write buffer operation.
6. In the pre-programming step of the Embedded Erase algorithm, all bits are programmed to 00h before erasure.
7. System-level overhead is the time required to execute the command sequence(s) for the program command. See Table 10.1 on page 51 and Table 10.3 on page 53 for further information on command definitions.

Table 16.1 TSOP Pin and BGA Package Capacitance

| Parameter Symbol | Parameter Description | Test Setup |  | Typ | Max | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{C}_{\text {IN }}$ | Input Capacitance | $\mathrm{V}_{\mathrm{IN}}=0$ | TSOP | 6 | 10 | pF |
|  |  |  | BGA | TBD | TBD | pF |
| Cout | Output Capacitance | $\mathrm{V}_{\text {OUT }}=0$ | TSOP | 6 | 12 | pF |
|  |  |  | BGA | TBD | TBD | pF |
| $\mathrm{C}_{\text {IN2 }}$ | Control Pin Capacitance | $\mathrm{V}_{\mathrm{IN}}=0$ | TSOP | 6 | 10 | pF |
|  |  |  | BGA | TBD | TBD | pF |
| $\mathrm{C}_{\text {IN3 }}$ | \#RESET, WP\#/ACC Pin Capacitance | $\mathrm{V}_{\mathrm{IN}}=0$ | TSOP | 27 | 30 | pF |
|  |  |  | BGA | TBD | TBD | pF |

## Notes

1. Sampled, not $100 \%$ tested.
2. Test conditions $T_{A}=25^{\circ} \mathrm{C}, f=1.0 \mathrm{MHz}$.

## 17. Physical Dimensions

### 17.1 TSO48-48-Pin Standard Thin Small Outline Package (TSOP)

STANDARD PIN OUT (TOP VIEW)

| Package | TS 048 |  |  |
| :---: | :---: | :---: | :---: |
| Jedec | MO-142 (B) EC |  |  |
| Symbol | MIN | NOM | MAX |
| A | - | - | 1.20 |
| A1 | 0.05 | - | 0.15 |
| A2 | 0.95 | 1.00 | 1.05 |
| b1 | 0.17 | 0.20 | 0.23 |
| b | 0.17 | 0.22 | 0.27 |
| C1 | 0.10 | - | 0.16 |
| C | 0.10 | - | 0.21 |
| D | 19.80 | 20.00 | 20.20 |
| D1 | 18.30 | 18.40 | 18.50 |
| E | 11.90 | 12.00 | 12.10 |
| e | 0.50 BASIC |  |  |
| L | 0.50 | 0.60 | 0.70 |
| O | $0^{\circ}$ | $3^{\circ}$ | $5^{\circ}$ |
| R | 0.08 | - | 0.20 |
| N | 48 |  |  |

NOTES:
1 CONTROLLING DIMENSIONS ARE IN MILLIMETERS (MM).
(DIMENSIONING AND TOLERANCING CONFORMS TO ANSI Y14.5M-1982)
2 PIN 1 IDENTIFIER FOR STANDARD PIN OUT (DIE UP),
3 NOT APPLICABLE.
4 TO BE DETERMINED AT THE SEATING PLANE -C-C. THE SEATING PLANE IS DEFINED AS THE PLANE OF CONTACT THAT IS MADE WHEN THE PACKAGE LEADS ARE ALLOWED TO REST FREELY ON A FLAT HORIZONTAL SURFACE.
5 DIMENSIONS D1 AND E DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE MOLD PROTUSION IS 0.15MM (.0059") PER SIDE.

6 DIMENSION b DOES NOT INCLUDE DAMBAR PROTUSION. ALLOWABLE DAMBAR PROTUSION SHALL BE 0.08 ( $0.0031^{\prime \prime}$ ) TOTAL IN EXCESS OF b DIMENSION AT MAX. MATERIAL CONDITION. MINIMUM SPACE BETWEEN PROTRUSION AND AN ADJACENT LEAD TO BE 0.07 ( $0.0028^{\prime \prime}$ ).
4 THESE DIMENSIONS APPLY TO THE FLAT SECTION OF THE LEAD BETWEEN 0.10 MM (.0039") AND 0.25 MM ( 0.0098 ") FROM THE LEAD TIP.

8 L
9. DIMENSION "e" IS MEASURED AT THE CENTERLINE OF THE LEADS

### 17.2 TS056-56-Pin Standard Thin Small Outline Package (TSOP)

| Package | TS 056 |  |  |
| :---: | :---: | :---: | :---: |
| Jedec | MO-142 (D) EC |  |  |
| Symbol | MIN | NOM | MAX |
| A | - | - | 1.20 |
| A1 | 0.05 | - | 0.15 |
| A2 | 0.95 | 1.00 | 1.05 |
| b1 | 0.17 | 0.20 | 0.23 |
| b | 0.17 | 0.22 | 0.27 |
| c1 | 0.10 | - | 0.16 |
| c | 0.10 | - | 0.21 |
| D | 19.80 | 20.00 | 20.20 |
| D1 | 18.30 | 18.40 | 18.50 |
| E | 13.90 | 14.00 | 14.10 |
| e | 0.50 BASIC |  |  |
| L | 0.50 | 0.60 | 0.70 |
| $\theta$ | $0^{\circ}$ | - | $8^{\circ}$ |
| R | 0.08 | - | 0.20 |
| N | 56 |  |  |

NOTES:
1 CONTROLLING DIMENSIONS ARE IN MILLIMETERS (mm).
1 (DIMENSIONING AND TOLERANCING CONFORMS TO ANSI Y14.5M-1982)
2 PIN 1 IDENTIFIER FOR REVERSE PIN OUT (DIE UP)
3 PIN 1 IDENTIFIER FOR REVERSE PIN OUT (DIE DOWN), INK OR LASER MARK
4 TO BE DETERMINED AT THE SEATING PLANE -C-. THE SEATING PLANE IS DEFINED AS THE PLANE OF CONTACT THAT IS MADE WHEN THE PACKAGE LEADS ARE ALLOWED TO REST FREELY ON A FLAT HORIZONTAL SURFACE.
5 DIMENSIONS D1 AND E DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE MOLD PROTUSION IS 0.15 mm (.0059") PER SIDE.

6 DIMENSION b DOES NOT INCLUDE DAMBAR PROTUSION. ALLOWABLE DAMBAR PROTUSION SHALL BE 0.08 ( $0.0031^{\prime \prime}$ ) TOTAL IN EXCESS OF b DIMENSION AT MAX. MATERIAL CONDITION. MINIMUM SPACE BETWEEN PROTRUSION AND AN ADJACENT LEAD TO BE 0.07 (0.0028").
4 THESE DIMENSIONS APPLY TO THE FLAT SECTION OF THE LEAD BETWEEN 0.10MM (.0039") AND 0.25MM (0.0098") FROM THE LEAD TIP.

8 LEAD COPLANARITY SHALL BE WITHIN 0.10 mm ( $0.004^{\prime \prime}$ ) AS MEASURED FROM THE SEATING PLANE.
9 DIMENSION "e" IS MEASURED AT THE CENTERLINE OF THE LEADS.

Data Shet

### 17.3 VBK048—Ball Fine-pitch Ball Grid Array (BGA) 8.15x 6.15 mm Package

| PACKAGE | VBK 048 |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| JEDEC | N/A |  |  |  |
|  | $8.15 \mathrm{~mm} \times 6.15 \mathrm{~mm}$ NOM PACKAGE |  |  |  |
| SYMBOL | MIN | NOM | MAX | NOTE |
| A | --- | --- | 1.00 | OVERALL THICKNESS |
| A1 | 0.18 | --- | --- | BALL HEIGHT |
| A2 | 0.62 | --- | 0.76 | BODY THICKNESS |
| D | 8.15 BSC. |  |  | BODY SIZE |
| E | 6.15 BSC. |  |  | BODY SIZE |
| D1 | 5.60 BSC. |  |  | BALL FOOTPRINT |
| E1 | 4.00 BSC. |  |  | BALL FOOTPRINT |
| MD | 8 |  |  | ROW MATRIX SIZE D DIRECTION |
| ME | 6 |  |  | ROW MATRIX SIZE E DIRECTION |
| N | 48 |  |  | TOTAL BALL COUNT |
| фb | 0.35 | --- | 0.43 | BALL DIAMETER |
| e | 0.80 BSC. |  |  | BALL PITCH |
| SD / SE | 0.40 BSC. |  |  | SOLDER BALL PLACEMENT |
|  | --- |  |  | DEPOPULATED SOLDER BALLS |

NOTES:

1. DIMENSIONING AND TOLERANCING PER ASME Y14.5M-1994
2. ALL DIMENSIONS ARE IN MILLIMETERS.
3. BALL POSITION DESIGNATION PER JESD 95-1, SPP-010 (EXCEPT AS NOTED).
4. e REPRESENTS THE SOLDER BALL GRID PITCH.
5. SYMBOL "MD" IS THE BALL ROW MATRIX SIZE IN THE "D" DIRECTION.
SYMBOL "ME" IS THE BALL COLUMN MATRIX SIZE IN THE "E" DIRECTION.

N IS THE TOTAL NUMBER OF SOLDER BALLS
6 DIMENSION "b" IS MEASURED AT THE MAXIMUM BALL DIAMETER IN A PLANE PARALLEL TO DATUM C
4 SD AND SE ARE MEASURED WITH RESPECT TO DATUMS A AND B AND DEFINE THE POSITION OF THE CENTER SOLDER BALL IN THE OUTER ROW.
WHEN THERE IS AN ODD NUMBER OF SOLDER BALLS IN THE OUTER ROW PARALLEL TO THE D OR E DIMENSION, RESPECTIVELY, SD OR SE $=0.000$.
WHEN THERE IS AN EVEN NUMBER OF SOLDER BALLS IN THE OUTER ROW, SD OR SE = e/2
8. NOT USED.
9. "+" INDICATES THE THEORETICAL CENTER OF DEPOPULATED BALLS.
10. A1 CORNER TO BE IDENTIFIED BY CHAMFER, LASER OR INK MARK, METALLIZED MARK INDENTATION OR OTHER MEANS.

### 17.4 LAA064-64-Ball Fortified Ball Grid Array (BGA) $13 \times 11$ mm Package

| PACKAGE | LAA 064 |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| JEDEC | N/A |  |  |  |
|  | $13.00 \mathrm{~mm} \times 11.00 \mathrm{~mm}$ PACKAGE |  |  |  |
| SYMBOL | MIN | NOM | MAX | NOTE |
| A | --- | --- | 1.40 | PROFILE HEIGHT |
| A1 | 0.40 | --- | --- | STANDOFF |
| A2 | 0.60 | --- | --- | BODY THICKNESS |
| D | 13.00 BSC. |  |  | BODY SIZE |
| E | 11.00 BSC. |  |  | BODY SIZE |
| D1 | 7.00 BSC. |  |  | MATRIX FOOTPRINT |
| E1 | 7.00 BSC. |  |  | MATRIX FOOTPRINT |
| MD | 8 |  |  | MATRIX SIZE D DIRECTION |
| ME | 8 |  |  | MATRIX SIZE E DIRECTION |
| N | 64 |  |  | BALL COUNT |
| ¢b | 0.50 | 0.60 | 0.70 | BALL DIAMETER |
| eD | 1.00 BSC . |  |  | BALL PITCH - D DIRECTION |
| eE | 1.00 BSC . |  |  | BALL PITCH - E DIRECTION |
| SD / SE | 0.50 BSC . |  |  | SOLDER BALL PLACEMENT |
|  | NONE |  |  | DEPOPULATED SOLDER BALLS |

NOTES:

1. DIMENSIONING AND TOLERANCING PER ASME Y14.5M-1994.
2. ALL DIMENSIONS ARE IN MILLIMETERS.
3. BALL POSITION DESIGNATION PER JESD 95-1, SPP-010 (EXCEPT AS NOTED).
4. e REPRESENTS THE SOLDER BALL GRID PITCH.
5. SYMBOL "MD" IS THE BALL ROW MATRIX SIZE IN THE "D" DIRECTION.

SYMBOL "ME" IS THE BALL COLUMN MATRIX SIZE IN THE "E" DIRECTION.
N IS THE TOTAL NUMBER OF SOLDER BALLS.
6 DIMENSION "b" IS MEASURED AT THE MAXIMUM BALL DIAMETER IN A PLANE PARALLEL TO DATUM C.
7 SD AND SE ARE MEASURED WITH RESPECT TO DATUMS A AND B AND DEFINE THE POSITION OF THE CENTER SOLDER BALL IN THE OUTER ROW.
WHEN THERE IS AN ODD NUMBER OF SOLDER BALLS IN THE OUTER ROW PARALLEL TO THE D OR E DIMENSION, RESPECTIVELY, SD OR SE $=0.000$.
WHEN THERE IS AN EVEN NUMBER OF SOLDER BALLS IN THE OUTER ROW, SD OR SE = e/2
8. NOT USED.
9. "+" INDICATES THE THEORETICAL CENTER OF DEPOPULATED BALLS.

### 17.5 LAE064-64-Ball Fortified Ball Grid Array (BGA) $9 \times 9$ mm Package

| PACKAGE | LAE 064 |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| JEDEC | N/A |  |  |  |
|  | $9.00 \mathrm{~mm} \times 9.00 \mathrm{~mm}$ <br> PACKAGE |  |  |  |
| SYMBOL | MIN | NOM | MAX | NOTE |
| A | --- | --- | 1.40 | PROFILE HEIGHT |
| A1 | 0.40 | --- | --- | STANDOFF |
| A2 | 0.60 | --- | --- | BODY THICKNESS |
| D | 9.00 BSC . |  |  | BODY SIZE |
| E | 9.00 BSC . |  |  | BODY SIZE |
| (1) | 7.00 BSC. |  |  | MATRIX FOOTPRINT |
| E1 | 7.00 BSC. |  |  | MATRIX FOOTPRINT |
| MD | 8 |  |  | MATRIX SIZE D DIRECTION |
| ME | 8 |  |  | MATRIX SIZE E DIRECTION |
| N | 64 |  |  | BALL COUNT |
| ¢b | 0.50 | 0.60 | 0.70 | BALL DIAMETER |
| eD | 1.00 BSC. |  |  | BALL PITCH - D DIRECTION |
| eE] | 1.00 BSC. |  |  | BALL PITCH - E DIRECTION |
| SD / SE | 0.50 BSC. |  |  | SOLDER BALL PLACEMENT |
|  | NONE |  |  | DEPOPULATED SOLDER BALLS |

NOTES:
. DIMENSIONING AND TOLERANCING PER ASME Y14.5M-1994
2. ALL DIMENSIONS ARE IN MILLIMETERS.
3. BALL POSITION DESIGNATION PER JESD 95-1, SPP-010 EXCEPT AS NOTED).
4. e REPRESENTS THE SOLDER BALL GRID PITCH.
5. SYMBOL "MD" IS THE BALL ROW MATRIX SIZE IN THE "D" DIRECTION.
SYMBOL "ME" IS THE BALL COLUMN MATRIX SIZE IN THE "E" DIRECTION.
N IS THE TOTAL NUMBER OF SOLDER BALLS.
6 DIMENSION "b" IS MEASURED AT THE MAXIMUM BALL DIAMETER IN A PLANE PARALLEL TO DATUM C.
7 SD AND SE ARE MEASURED WITH RESPECT TO DATUMS A AND B AND DEFINE THE POSITION OF THE CENTER SOLDER BALL IN THE OUTER ROW.
WHEN THERE IS AN ODD NUMBER OF SOLDER BALLS IN THE OUTER ROW PARALLEL TO THE D OR E DIMENSION, RESPECTIVELY, SD OR SE $=0.000$.
WHEN THERE IS AN EVEN NUMBER OF SOLDER BALLS IN THE OUTER ROW, SD OR SE = e/2
8. NOT USED
9. "+" INDICATES THE THEORETICAL CENTER OF DEPOPULATED BALLS.

## 18. Revision History

| Section | Description |
| :---: | :---: |
| Revision 01 (February 12, 2007) |  |
|  | Initial release. |
| Revision 02 (February 26, 2007) |  |
| Global | Replaced LAE064 package with LAA064. |
| Page Mode Read | Corrected bit ranges in first paragraph. |
| Erase And Programming Performance | Modified maximum sector erase time in table. |
| Revision 03 (March 15, 2007) |  |
| Connection Diagrams | 64-ball Fortified BGA (LAA 064) figure: Changed inputs for balls F1 and F7. |
| Revision 04 (July 6, 2007) |  |
| Ordering Information | Removed regulated $\mathrm{V}_{\text {CC }}$ range and replaced 90 ns with 110 ns for low $\mathrm{V}_{\text {IO }}$ option |
|  | Added Note 4 to PACKAGE MATERIAL SET Standard option |
| Sector Addresses table | Corrected a table |
| TSOP Pin and BGA Package Capacitance | Added values for TSOP |
| Revision 05 (August 10, 2007) |  |
| Ordering Information | Removed leaded parts |
| CFI Table | Altered Erase Block Region 1 \& 2 |
| Revision 06 (September 18, 2007) |  |
| Global | Change document status to Full Production |
|  | Removed 70ns access speed |
| Command Definitions (x16 mode) Table | Corrected addresses for Program operation |
| Command Definitions (x8 mode) Table | Corrected addresses for Program operation |
| Revision 07 (October 22, 2007) |  |
| Global | Removed VID (12V) Sector protect \& unprotect features |
| Primary Vendor-Specific Extended Query Table | Updated the data of CFI address 45hex |
| Revision 08 (November 2, 2007) |  |
| Primary Vendor-Specific Extended Query Table | Updated the data of CFI address 2D hex thru 34 hex. |
| S29GL064N (Model 04) Bottom Boot Sector Addresses Table | Updated S29GL064N (Model 04) Bottom Boot Sector Addresses |
| Revision 09 (November 16, 2007) |  |
| Erase and Program Operations Table | Changed $\mathrm{t}_{\mathrm{DS}}$ from 45 ns to 35 ns |
| Revision 10 (April 10, 2008) |  |
| Absolute Maximum Rating | Removed OE\# form table and notes |
| Alternate CE\# Controlled Erase and Program Operations | Changed $\mathrm{t}_{\mathrm{DS}}$ from 45 ns to 35 ns Changed $\mathrm{t}_{\mathrm{CPH}}$ from 30 ns to 25 ns |
| Requirements for Reading Array Data | Entire section is re-written to explain requirements for reading array data |
| Sector Protection | Title changed to Advanced Sector Protection |
| Advanced Sector Protection | Section removed |
| Erase and Program Operations | Removed note 4 |
| Alternate CE\# Controlled Erase and Program Operations | Removed note 4 |
| Global | Corrected minor typos |
| AC Characteristics | Updated Data\#Polling Timing |

| Section | Description |  |
| :--- | :--- | :---: |
| Revision 11 (August 5, 2008) | Changed Note 1 in Table DC Characteristics- CMOS Compatible |  |
| DC Characteristics | Added LAE064 package option |  |
| Ordering Information | Figure 3.3; Title changed to 64ball Fortified BGA |  |
| Connection Diagram | Added LAE064 package option |  |
| Physical Dimensions |  |  |
| Revision 12 (October 29, 2008) | Updated Valid Combinations Table |  |

## Colophon

The products described in this document are designed, developed and manufactured as contemplated for general use, including without limitation, ordinary industrial use, general office use, personal use, and household use, but are not designed, developed and manufactured as contemplated (1) for any use that includes fatal risks or dangers that, unless extremely high safety is secured, could have a serious effect to the public, and could lead directly to death, personal injury, severe physical damage or other loss (i.e., nuclear reaction control in nuclear facility, aircraft flight control, air traffic control, mass transport control, medical life support system, missile launch control in weapon system), or (2) for any use where chance of failure is intolerable (i.e., submersible repeater and artificial satellite). Please note that Spansion will not be liable to you and/or any third party for any claims or damages arising in connection with above-mentioned uses of the products. Any semiconductor devices have an inherent chance of failure. You must protect against injury, damage or loss from such failures by incorporating safety design measures into your facility and equipment such as redundancy, fire protection, and prevention of over-current levels and other abnormal operating conditions. If any products described in this document represent goods or technologies subject to certain restrictions on export under the Foreign Exchange and Foreign Trade Law of Japan, the US Export Administration Regulations or the applicable laws of any other country, the prior authorization by the respective government entity will be required for export of those products.

## Trademarks and Notice

The contents of this document are subject to change without notice. This document may contain information on a Spansion product under development by Spansion. Spansion reserves the right to change or discontinue work on any product without notice. The information in this document is provided as is without warranty or guarantee of any kind as to its accuracy, completeness, operability, fitness for particular purpose, merchantability, non-infringement of third-party rights, or any other warranty, express, implied, or statutory. Spansion assumes no liability for any damages of any kind arising out of the use of the information in this document.

[^0]:    Notes

    1. See Table 10.1 and Table 10.3 for program command sequence.
    2. See the section on DQ3 for information on the sector erase timer.
[^1]:    Notes

    1. Operating ranges define those limits between which the functionality of the device is guaranteed.
    2. $V_{I O}$ input voltage always must be lower than $V_{C C}$ input voltage.
