

8-BIT LOW-POWER, FULL-SPEED USB MCU WITH 16K FLASH, 768 RAM, SMARTCARD I/F, TIMER

■ Memories

- Up to 16K of ROM or High Density Flash (HD-Flash) program memory with read/write protection, HDFlash In-Circuit and In-Application Programming. 100 write/erase cycles guaranteed, data retention: 20 years at 55°C
- Up to 768 bytes of RAM including up to 128 bytes stack and 256 bytes USB buffer

■ Clock, Reset and Supply Management

- Low Voltage Reset
- 2 power saving modes: Halt and Wait modes
- PLL for generating 48 MHz USB clock using a 4 MHz crystal

■ Interrupt Management

- Nested Interrupt Controller

■ USB (Universal Serial Bus) Interface

- 256-byte buffer for full speed bulk, control and interrupt transfer types compliant with USB specification (version 2.0)
- On-Chip 3.3V USB voltage regulator and transceivers with software power-down
- 7 USB Endpoints:
 - One 8-byte Bidirectional Control Endpoint
 - One 64-byte In Endpoint,
 - One 64-byte Out Endpoint
 - Four 8-byte In Endpoints

■ 35 or 4 I/O ports:

- Up to 4 LED outputs with software programmable constant current (3 or 7 mA).
- 2 General purpose I/Os programmable as interrupts
- Up to 8 line inputs programmable as interrupts
- Up to 20 Outputs
- 1 line assigned by default as static input after reset

■ ISO7816-3 UART Interface:

- 4 Mhz Clock generation
- Synchronous/Asynchronous protocols (T=0, T=1)
- Automatic retry on parity error
- Programmable Baud rate from 372 clock pulses up to 11.625 clock pulses (D=32/F=372)
- Card Insertion/Removal Detection

■ Smartcard Power Supply:

- Selectable card V_{CC} 1.8V, 3V, and 5V
- Internal Step-up converter for 5V supplied Smartcards (with a current of up to 55mA) using only two external components.
- Programmable Smartcard Internal Voltage Regulator (1.8V to 3.0V) with current overload protection and 4 KV ESD protection (Human Body Model) for all Smartcard Interface I/Os

■ One 8-bit Timer

- Time Base Unit (TBU) for generating periodic interrupts.

■ Development Tools

- Full hardware/software development package

Table 1. Device Summary

Features	ST7FSCR1R4	ST7SCR1R4	ST7FSCR1E4	ST7SCR1E4
Program memory	16K FLASH	16K ROM	16K FLASH	16K ROM
User RAM (stack) - bytes	768 (128)			
Peripherals	USB Full-Speed (7 Ep), TBU, Watchdog timer, ISO7816-3 Interface			
Operating Supply	4.0 to 5.5V			
Package	TQFP64		SO24	
CPU Frequency	4 or 8 Mhz			
Operating temperature	0°C to +70°C

1 INTRODUCTION

The ST7SCR and ST7FSCR devices are members of the ST7 microcontroller family designed for USB applications. All devices are based on a common industry-standard 8-bit core, featuring an enhanced instruction set.

The ST7SCR ROM devices are factory-programmed and are not reprogrammable.

The ST7FSCR versions feature dual-voltage Flash memory with Flash Programming capability.

They operate at a 4MHz external oscillator frequency.

Under software control, all devices can be placed in WAIT or HALT mode, reducing power consumption when the application is in idle or stand-by state.

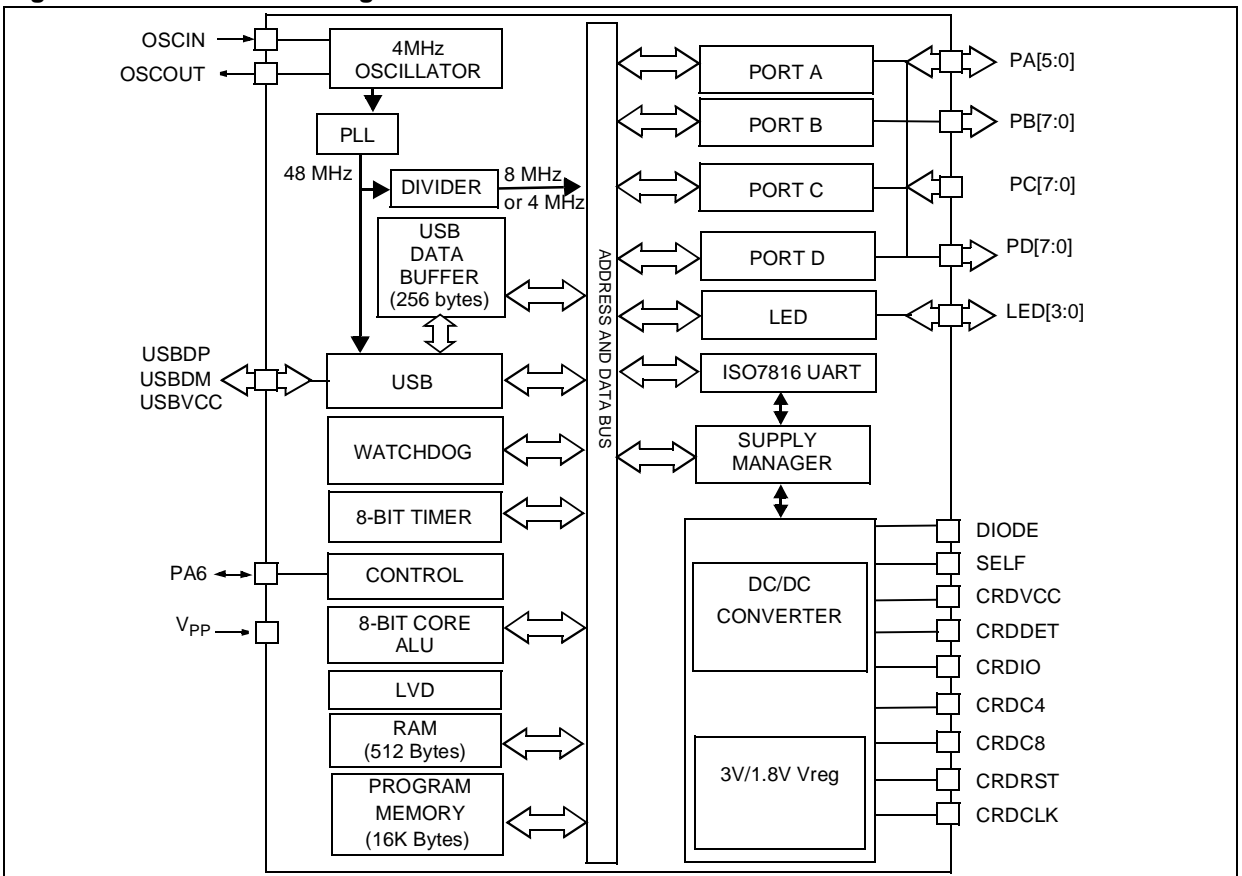

The enhanced instruction set and addressing modes of the ST7 offer both power and flexibility to software developers, enabling the design of highly efficient and compact application code. In addition to standard 8-bit data management, all ST7 microcontrollers feature true bit manipulation, 8x8 un-

signed multiplication and indirect addressing modes.

The devices include an ST7 Core, up to 16 Kbytes of program memory, up to 512 bytes of user RAM, up to 35 I/O lines and the following on-chip peripherals:

- USB full speed interface with 7 endpoints, programmable in/out configuration and embedded 3.3V voltage regulator and transceivers (no external components are needed).
- ISO7816-3 UART interface with Programmable Baud rate from 372 clock pulses up to 11.625 clock pulses
- Smartcard Supply Block able to provide programmable supply voltage and I/O voltage levels to the smartcards
- Low voltage reset ensuring proper power-on or power-off of the device (selectable by option)
- Watchdog Timer
- 8-bit Timer (TBU)

PIN DESCRIPTION (Cont'd)

Legend / Abbreviations:

Type: I = input, O = output, S = supply

In/Output level: C_T = CMOS $0.3V_{DD}/0.7V_{DD}$ with input trigger

Output level: HS = 10mA high sink (on N-buffer only)

Port and control configuration:

– Input: float = floating, wpu = weak pull-up, int = interrupt, ana = analog

– Output: OD = open drain, PP = push-pull

Refer to "I/O PORTS" on page 30 for more details on the software configuration of the I/O ports.

Note 1: Refer to Section 6 on page 20.

3 REGISTER & MEMORY MAP

As shown in Figure 5, the MCU is capable of addressing 64K bytes of memories and I/O registers.

The available memory locations consist of 40 bytes of register locations, up to 512 bytes of RAM and up to 16K bytes of user program memory. The RAM space includes up to 128 bytes for the stack from 0100h to 017Fh.

The highest address bytes contain the user reset and interrupt vectors.

IMPORTANT: Memory locations noted “Reserved” must never be accessed. Accessing a reserved area can have unpredictable effects on the device.

4 FLASH PROGRAM MEMORY

4.1 Introduction

The ST7 dual voltage High Density Flash (HD-Flash) is a non-volatile memory that can be electrically erased as a single block or by individual sectors and programmed on a Byte-by-Byte basis using an external V_{PP} supply.

The HDFlash devices can be programmed and erased off-board (plugged in a programming tool) or on-board using ICP (In-Circuit Programming) or IAP (In-Application Programming).

The array matrix organisation allows each sector to be erased and reprogrammed without affecting other sectors.

4.2 Main Features

- Three Flash programming modes:
 - Insertion in a programming tool. In this mode, all sectors including option bytes can be programmed or erased.
 - ICP (In-Circuit Programming). In this mode, all sectors including option bytes can be programmed or erased without removing the device from the application board.
 - IAP (In-Application Programming) In this mode, all sectors except Sector 0, can be programmed or erased without removing the device from the application board and while the application is running.
- ICT (In-Circuit Testing) for downloading and executing user application test patterns in RAM
- Read-out protection against piracy
- Register Access Security System (RASS) to prevent accidental programming or erasing

4.3 Structure

The Flash memory is organised in sectors and can be used for both code and data storage.

Depending on the overall FLASH memory size in the microcontroller device, there are up to three

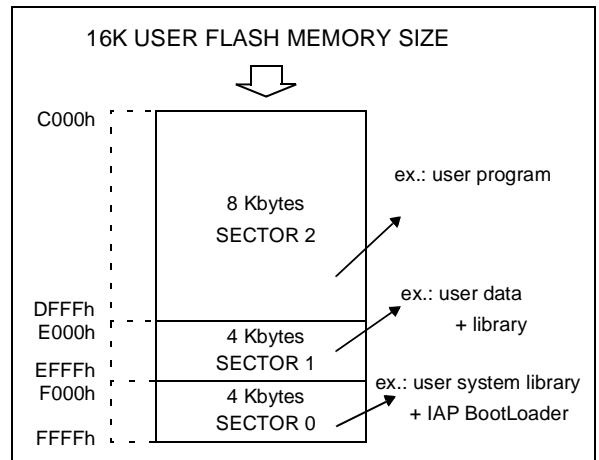

user sectors (see Table 3). Each of these sectors can be erased independently to avoid unnecessary erasing of the whole Flash memory when only a partial erasing is required.

The first two sectors have a fixed size of 4 Kbytes (see Figure 6). They are mapped in the upper part of the ST7 addressing space so the reset and interrupt vectors are located in Sector 0 (F000h-FFFFh).

Table 3. Sectors available in FLASH devices

Flash Memory Size (bytes)	Available Sectors
4K	Sector 0
8K	Sectors 0,1
> 8K	Sectors 0,1, 2

Figure 6. Memory map and sector address

FLASH PROGRAM MEMORY (Cont'd)

4.4 ICP (In-Circuit Programming)

To perform ICP the microcontroller must be switched to ICC (In-Circuit Communication) mode by an external controller or programming tool.

Depending on the ICP code downloaded in RAM, Flash memory programming can be fully customized (number of bytes to program, program locations, or selection serial communication interface for downloading).

When using an STMicroelectronics or third-party programming tool that supports ICP and the specific microcontroller device, the user needs only to implement the ICP hardware interface on the application board (see Figure 7). For more details on the pin locations, refer to the device pinout description.

ICP needs six signals to be connected to the programming tool. These signals are:

- V_{SS} : device power supply ground
- V_{DD} : for reset by LVD
- OSCIN: to force the clock during power-up
- ICCCLK: ICC output serial clock pin
- ICCDATA: ICC input serial data pin
- V_{PP} : ICC mode selection and programming voltage.

If ICCCLK or ICCDATA are used for other purposes in the application, a serial resistor has to be implemented to avoid a conflict in case one of the other devices forces the signal level.

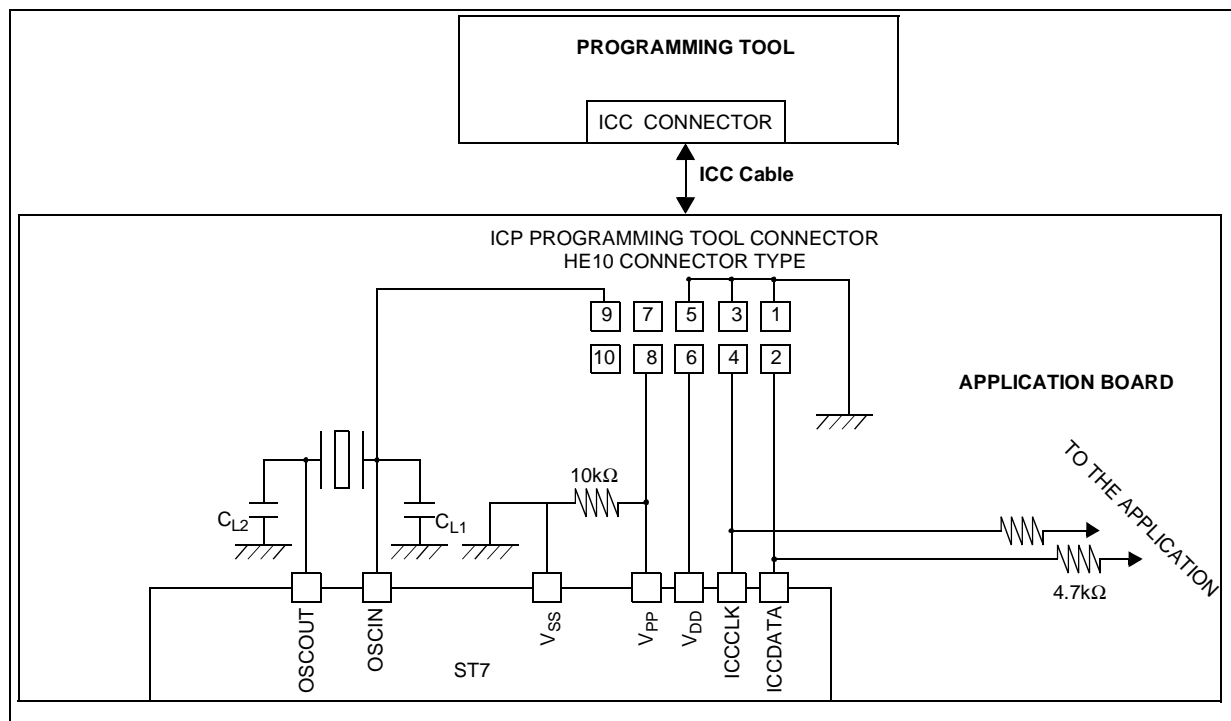

Note: To develop a custom programming tool, refer to the ST7 FLASH Programming and ICC Reference Manual which gives full details on the ICC protocol hardware and software.

4.5 IAP (In-Application Programming)

This mode uses a BootLoader program previously stored in Sector 0 by the user (in ICP mode or by plugging the device in a programming tool).

This mode is fully controlled by user software. This allows it to be adapted to the user application, (user-defined strategy for entering programming mode, choice of communications protocol used to fetch the data to be stored, etc.). For example, it is possible to download code from the USB interface and program it in the Flash. IAP mode can be used to program any of the Flash sectors except Sector 0, which is write/erase protected to allow recovery in case errors occur during the programming operation.

Figure 7. Typical ICP Interface

FLASH PROGRAM MEMORY (Cont'd)

Note: If the ICCCLK or ICCDATA pins are only used as outputs in the application, no signal isolation is necessary. As soon as the Programming Tool is plugged to the board, even if an ICC session is not in progress, the ICCCLK and ICCDATA pins are not available for the application. If they are used as inputs by the application, isolation such as a serial resistor has to be implemented in case another device forces the signal. Refer to the Programming Tool documentation for recommended resistor values.

4.6 Program Memory Read-out Protection

The read-out protection is enabled through an option bit.

For Flash devices, when this option is selected, the program and data stored in the Flash memory are protected against read-out piracy (including a re-write protection). When this protection is removed by reprogramming the Option Byte, the en-

tire Flash program memory is first automatically erased.

Refer to the Option Byte description for more details.

4.6.1 Register Description

FLASH CONTROL/STATUS REGISTER (FCSR)

Read/Write

Reset Value: 0000 0000 (00h)

7							0
0	0	0	0	0	0	0	0

This register is reserved for use by Programming Tool software. It controls the FLASH programming and erasing operations. For details on customizing FLASH programming methods and In-Circuit Testing, refer to the ST7 FLASH Programming and ICC Reference Manual.

5 CENTRAL PROCESSING UNIT

5.1 INTRODUCTION

This CPU has a full 8-bit architecture and contains six internal registers allowing efficient 8-bit data manipulation.

5.2 MAIN FEATURES

- Enable executing 63 basic instructions
- Fast 8-bit by 8-bit multiply
- 17 main addressing modes (with indirect addressing mode)
- Two 8-bit index registers
- 16-bit stack pointer
- Low power HALT and WAIT modes
- Priority maskable hardware interrupts
- Non-maskable software/hardware interrupts

5.3 CPU REGISTERS

The 6 CPU registers shown in Figure 8 are not present in the memory mapping and are accessed by specific instructions.

Accumulator (A)

The Accumulator is an 8-bit general purpose register used to hold operands and the results of the arithmetic and logic calculations and to manipulate data.

Index Registers (X and Y)

These 8-bit registers are used to create effective addresses or as temporary storage areas for data manipulation. (The Cross-Assembler generates a precede instruction (PRE) to indicate that the following instruction refers to the Y register.)

The Y register is not affected by the interrupt automatic procedures.

Program Counter (PC)

The program counter is a 16-bit register containing the address of the next instruction to be executed by the CPU. It is made of two 8-bit registers PCL (Program Counter Low which is the LSB) and PCH (Program Counter High which is the MSB).

Figure 8. CPU Registers

CENTRAL PROCESSING UNIT (Cont'd)

Condition Code Register (CC)

Read/Write

Reset Value: 111x1xxx

7							0
1	1	I1	H	I0	N	Z	C

The 8-bit Condition Code register contains the interrupt masks and four flags representative of the result of the instruction just executed. This register can also be handled by the PUSH and POP instructions.

These bits can be individually tested and/or controlled by specific instructions.

Arithmetic Management Bits

Bit 4 = **H** *Half carry*.

This bit is set by hardware when a carry occurs between bits 3 and 4 of the ALU during an ADD or ADC instructions. It is reset by hardware during the same instructions.

- 0: No half carry has occurred.
- 1: A half carry has occurred.

This bit is tested using the JRH or JRNH instruction. The H bit is useful in BCD arithmetic subroutines.

Bit 2 = **N** *Negative*.

This bit is set and cleared by hardware. It is representative of the result sign of the last arithmetic, logical or data manipulation. It's a copy of the result 7th bit.

- 0: The result of the last operation is positive or null.
- 1: The result of the last operation is negative (i.e. the most significant bit is a logic 1).

This bit is accessed by the JRMI and JRPL instructions.

Bit 1 = **Z** *Zero*.

This bit is set and cleared by hardware. This bit indicates that the result of the last arithmetic, logical or data manipulation is zero.

- 0: The result of the last operation is different from zero.
- 1: The result of the last operation is zero.

This bit is accessed by the JREQ and JRNE test instructions.

Bit 0 = **C** *Carry/borrow*.

This bit is set and cleared by hardware and software. It indicates an overflow or an underflow has occurred during the last arithmetic operation.

- 0: No overflow or underflow has occurred.
- 1: An overflow or underflow has occurred.

This bit is driven by the SCF and RCF instructions and tested by the JRC and JRNC instructions. It is also affected by the "bit test and branch", shift and rotate instructions.

Interrupt Management Bits

Bit 5,3 = **I1, I0** *Interrupt*

The combination of the I1 and I0 bits gives the current interrupt software priority.

Interrupt Software Priority	I1	I0
Level 0 (main)	1	0
Level 1	0	1
Level 2	0	0
Level 3 (= interrupt disable)	1	1

These two bits are set/cleared by hardware when entering in interrupt. The loaded value is given by the corresponding bits in the interrupt software priority registers (IxSPR). They can be also set/cleared by software with the RIM, SIM, IRET, HALT, WFI and PUSH/POP instructions.

See the interrupt management chapter for more details.

6 SUPPLY, RESET AND CLOCK MANAGEMENT

6.1 CLOCK SYSTEM

6.1.1 General Description

The MCU accepts either a 4MHz crystal or an external clock signal to drive the internal oscillator. The internal clock (f_{CPU}) is derived from the internal oscillator frequency (f_{OSC}), which is 4MHz.

After reset, the internal clock (f_{CPU}) is provided by the internal oscillator (4MHz frequency).

To activate the 48-MHz clock for the USB interface, the user must turn on the PLL by setting the PLL_ON bit in the MISCR4 register. When the PLL is locked, the LOCK bit is set by hardware.

The user can then select an internal frequency (f_{CPU}) of either 4 MHz or 8MHz by programming the CLK_SEL bit in the MISCR4 register (refer to MISCELLANEOUS REGISTERS section on page 37).

The PLL provides a signal with a duty cycle of 50%.

The internal clock signal (f_{CPU}) is also routed to the on-chip peripherals. The CPU clock signal consists of a square wave with a duty cycle of 50%.

Figure 10. Clock, Reset and Supply Block Diagram

The internal oscillator is designed to operate with an AT-cut parallel resonant quartz in the frequency range specified for f_{OSC} . The circuit shown in Figure 12 is recommended when using a crystal, and Table 4 lists the recommended capacitance. The crystal and associated components should be mounted as close as possible to the input pins in order to minimize output distortion and start-up stabilisation time. The LOCK bit in the MISCR4 register can also be used to generate the f_{CPU} directly from f_{OSC} if the PLL and the USB interface are not active.

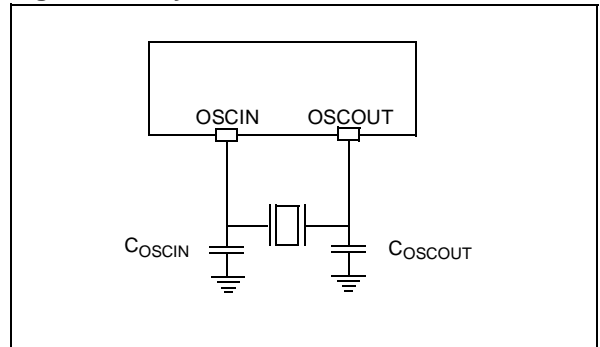

Table 4. Recommended Values for 4 MHz Crystal Resonator

$R_{S_{MAX}}$	20 Ω	25 Ω	70 Ω
C_{OSCIN}	56pF	47pF	22pF
C_{OSCOUT}	56pF	47pF	22pF

Note: $R_{S_{MAX}}$ is the equivalent serial resistor of the crystal (see crystal specification).

CLOCK SYSTEM (Cont'd)**6.1.2 External Clock**

An external clock may be applied to the OSCIN input with the OSCOUT pin not connected, as shown on Figure 11.

Figure 11. .External Clock Source Connections**Figure 12. Crystal Resonator**

6.2 RESET SEQUENCE MANAGER (RSM)

6.2.1 Introduction

The reset sequence manager has two reset sources:

- Internal LVD reset (Low Voltage Detection) which includes both a power-on and a voltage drop reset
- Internal watchdog reset generated by an internal watchdog counter underflow as shown in Figure 14.

6.2.2 Functional Description

The reset service routine vector is fixed at addresses FFFEh-FFFFh in the ST7 memory map.

The basic reset sequence consists of 3 phases as shown in Figure 13:

- A first delay of $30\mu\text{s} + 127 t_{\text{CPU}}$ cycles during which the internal reset is maintained.
- A second delay of $512 t_{\text{CPU}}$ cycles after the internal reset is generated. It allows the oscillator to stabilize and ensures that recovery has taken place from the Reset state.
- Reset vector fetch (duration: 2 clock cycles)

Low Voltage Detector

The low voltage detector generates a reset when $V_{\text{DD}} < V_{\text{IT}+}$ (rising edge) or $V_{\text{DD}} < V_{\text{IT}-}$ (falling edge), as shown in Figure 13.

The LVD filters spikes on V_{DD} larger than $t_{\text{g}}(V_{\text{DD}})$ to avoid parasitic resets. See "SUPPLY AND RESET CHARACTERISTICS" on page 79.

Figure 13. LVD RESET Sequence

Figure 14. Watchdog RESET Sequence

7 INTERRUPTS

7.1 INTRODUCTION

The ST7 enhanced interrupt management provides the following features:

- Hardware interrupts
- Software interrupt (TRAP)
- Nested or concurrent interrupt management with flexible interrupt priority and level management:
 - Up to 4 software programmable nesting levels
 - Up to 16 interrupt vectors fixed by hardware
 - 3 non maskable events: TLI, RESET, TRAP

This interrupt management is based on:

- Bit 5 and bit 3 of the CPU CC register (I1:0),
- Interrupt software priority registers (ISPRx),
- Fixed interrupt vector addresses located at the high addresses of the memory map (FFE0h to FFFFh) sorted by hardware priority order.

This enhanced interrupt controller guarantees full upward compatibility with the standard (not nested) ST7 interrupt controller.

7.2 MASKING AND PROCESSING FLOW

The interrupt masking is managed by the I1 and I0 bits of the CC register and the ISPRx registers which give the interrupt software priority level of each interrupt vector (see Table 5). The processing flow is shown in Figure 15.

When an interrupt request has to be serviced:

- Normal processing is suspended at the end of the current instruction execution.
- The PC, X, A and CC registers are saved onto the stack.
- I1 and I0 bits of CC register are set according to the corresponding values in the ISPRx registers of the serviced interrupt vector.
- The PC is then loaded with the interrupt vector of the interrupt to service and the first instruction of the interrupt service routine is fetched (refer to "Interrupt Mapping" table for vector addresses).

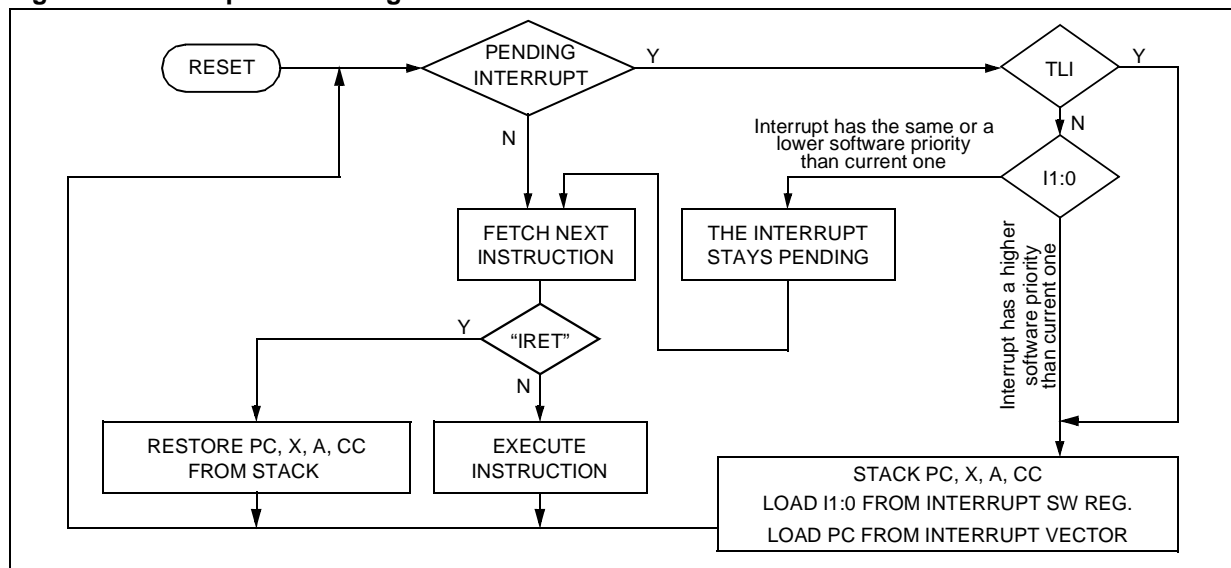

The interrupt service routine should end with the IRET instruction which causes the contents of the saved registers to be recovered from the stack.

Note: As a consequence of the IRET instruction, the I1 and I0 bits will be restored from the stack and the program in the previous level will resume.

Table 5. Interrupt Software Priority Levels

Interrupt software priority	Level	I1	I0
Level 0 (main)	Low	1	0
Level 1	↓	0	1
Level 2		0	0
Level 3 (= interrupt disable)	High	1	1

Figure 15. Interrupt Processing Flowchart

INTERRUPTS (Cont'd)

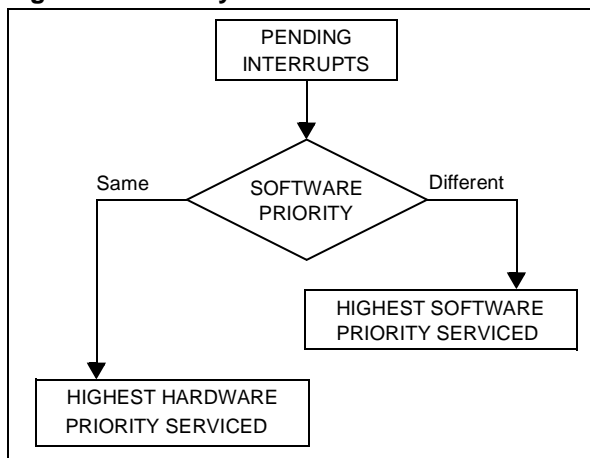

Servicing Pending Interrupts

As several interrupts can be pending at the same time, the interrupt to be taken into account is determined by the following two-step process:

- the highest software priority interrupt is serviced,
- if several interrupts have the same software priority then the interrupt with the highest hardware priority is serviced first.

Figure 16 describes this decision process.

Figure 16. Priority Decision Process

When an interrupt request is not serviced immediately, it is latched and then processed when its software priority combined with the hardware priority becomes the highest one.

Note 1: The hardware priority is exclusive while the software one is not. This allows the previous process to succeed with only one interrupt.

Note 2: RESET, TRAP and TLI are non maskable and they can be considered as having the highest software priority in the decision process.

Different Interrupt Vector Sources

Two interrupt source types are managed by the ST7 interrupt controller: the non-maskable type (RESET, TLI, TRAP) and the maskable type (external or from internal peripherals).

Non-Maskable Sources

These sources are processed regardless of the state of the I1 and I0 bits of the CC register (see Figure 15). After stacking the PC, X, A and CC registers (except for RESET), the corresponding vector is loaded in the PC register and the I1 and I0 bits of the CC are set to disable interrupts (level 3). These sources allow the processor to exit HALT mode.

■ TLI (Top Level Hardware Interrupt)

This hardware interrupt occurs when a specific edge is detected on the dedicated TLI pin.

Caution: A TRAP instruction must not be used in a TLI service routine.

■ TRAP (Non Maskable Software Interrupt)

This software interrupt is serviced when the TRAP instruction is executed. It will be serviced according to the flowchart in Figure 15 as a TLI.

Caution: TRAP can be interrupted by a TLI.

■ RESET

The RESET source has the highest priority in the ST7. This means that the first current routine has the highest software priority (level 3) and the highest hardware priority.

See the RESET chapter for more details.

Maskable Sources

Maskable interrupt vector sources can be serviced if the corresponding interrupt is enabled and if its own interrupt software priority (in ISPRx registers) is higher than the one currently being serviced (I1 and I0 in CC register). If any of these two conditions is false, the interrupt is latched and thus remains pending.

■ External Interrupts

External interrupts allow the processor to exit from HALT low power mode.

External interrupt sensitivity is software selectable through the External Interrupt Control register (EICR).

External interrupt triggered on edge will be latched and the interrupt request automatically cleared upon entering the interrupt service routine.

If several input pins of a group connected to the same interrupt line are selected simultaneously, these will be logically Nanded.

■ Peripheral Interrupts

Usually the peripheral interrupts cause the MCU to exit from HALT mode except those mentioned in the "Interrupt Mapping" table.

A peripheral interrupt occurs when a specific flag is set in the peripheral status registers and if the corresponding enable bit is set in the peripheral control register.

The general sequence for clearing an interrupt is based on an access to the status register followed by a read or write to an associated register.

Note: The clearing sequence resets the internal latch. A pending interrupt (i.e. waiting for being serviced) will therefore be lost if the clear sequence is executed.

INTERRUPTS (Cont'd)

7.3 INTERRUPTS AND LOW POWER MODES

All interrupts allow the processor to exit the WAIT low power mode. On the contrary, only external and other specified interrupts allow the processor to exit from the HALT modes (see column "Exit from HALT" in "Interrupt Mapping" table). When several pending interrupts are present while exiting HALT mode, the first one serviced can only be an interrupt with exit from HALT mode capability and it is selected through the same decision process shown in Figure 16.

Note: If an interrupt, that is not able to Exit from HALT mode, is pending with the highest priority when exiting HALT mode, this interrupt is serviced after the first one serviced.

7.4 CONCURRENT & NESTED MANAGEMENT

The following Figure 17 and Figure 18 show two different interrupt management modes. The first is called concurrent mode and does not allow an interrupt to be interrupted, unlike the nested mode in Figure 18. The interrupt hardware priority is given in this order from the lowest to the highest: MAIN, IT4, IT3, IT2, IT1, IT0, TLI. The software priority is given for each interrupt.

Warning: A stack overflow may occur without notifying the software of the failure.

Figure 17. Concurrent Interrupt Management

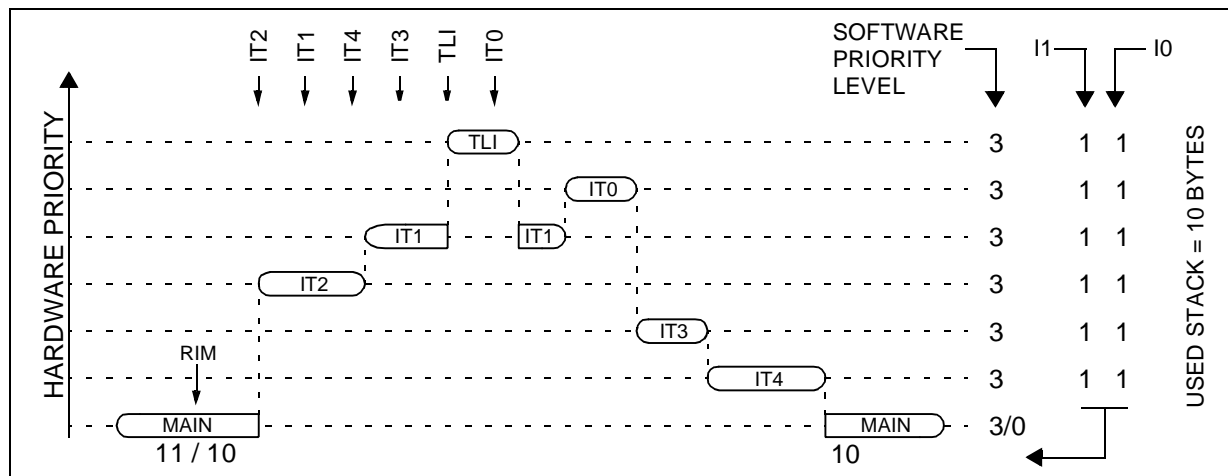

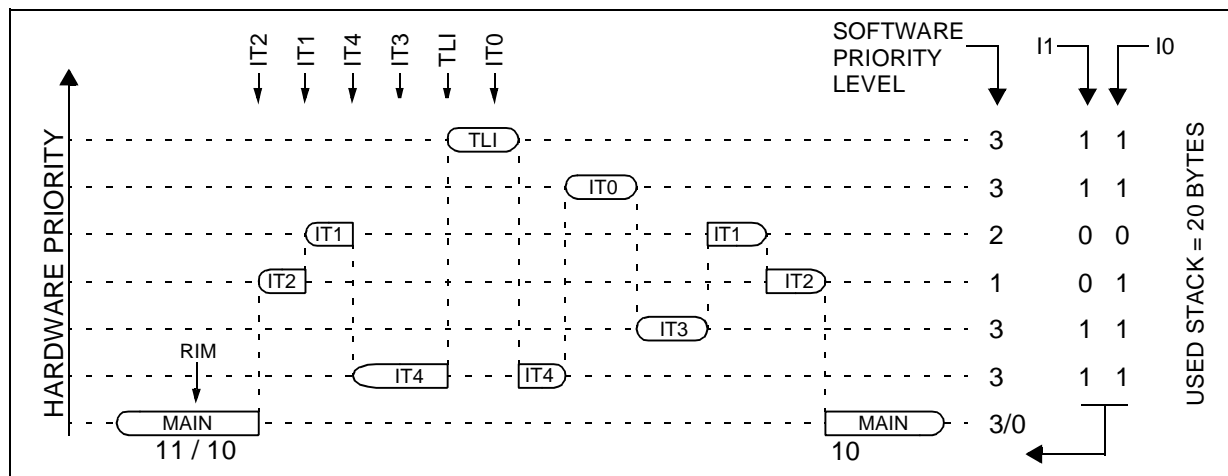

Figure 18. Nested Interrupt Management

INTERRUPTS (Cont'd)

7.5 INTERRUPT REGISTER DESCRIPTION

CPU CC REGISTER INTERRUPT BITS

Read/Write

Reset Value: 111x 1010 (xAh)

7								0						
1	1	I1	H	I0	N	Z	C							

Bit 5, 3 = I1, I0 Software Interrupt Priority

These two bits indicate the current interrupt software priority.

Interrupt Software Priority	Level	I1	I0
Level 0 (main)	Low	1	0
Level 1	↓	0	1
Level 2		0	0
Level 3 (= interrupt disable*)		High	1

These two bits are set/cleared by hardware when entering in interrupt. The loaded value is given by the corresponding bits in the interrupt software priority registers (ISPRx).

They can be also set/cleared by software with the RIM, SIM, HALT, WFI, IRET and PUSH/POP instructions (see "Interrupt Dedicated Instruction Set" table).

***Note:** TLI, TRAP and RESET events are non maskable sources and can interrupt a level 3 program.

INTERRUPT SOFTWARE PRIORITY REGISTERS (ISPRX)

Read/Write (bit 7:4 of ISPR3 are read only)

Reset Value: 1111 1111 (FFh)

7								0						
ISPR0	I1_3	I0_3	I1_2	I0_2	I1_1	I0_1	I1_0	I0_0						
ISPR1	I1_7	I0_7	I1_6	I0_6	I1_5	I0_5	I1_4	I0_4						
ISPR2	I1_11	I0_11	I1_10	I0_10	I1_9	I0_9	I1_8	I0_8						
ISPR3	1	1	1	1	I1_13	I0_13	I1_12	I0_12						

These four registers contain the interrupt software priority of each interrupt vector.

– Each interrupt vector (except RESET and TRAP) has corresponding bits in these registers where its own software priority is stored. This correspondence is shown in the following table.

Vector address	ISPRx bits
FFFBh-FFFAh	I1_0 and I0_0 bits*
FFF9h-FFF8h	I1_1 and I0_1 bits
...	...
FFE1h-FFE0h	I1_13 and I0_13 bits

– Each I1_x and I0_x bit value in the ISPRx registers has the same meaning as the I1 and I0 bits in the CC register.

– Level 0 can not be written (I1_x=1, I0_x=0). In this case, the previously stored value is kept. (example: previous=CFh, write=64h, result=44h)

The RESET, TRAP and TLI vectors have no software priorities. When one is serviced, the I1 and I0 bits of the CC register are both set.

***Note:** Bits in the ISPRx registers which correspond to the TLI can be read and written but they are not significant in the interrupt process management.

Caution: If the I1_x and I0_x bits are modified while the interrupt x is executed the following behaviour has to be considered: If the interrupt x is still pending (new interrupt or flag not cleared) and the new software priority is higher than the previous one, the interrupt x is re-entered. Otherwise, the software priority stays unchanged up to the next interrupt request (after the IRET of the interrupt x).

INTERRUPTS (Cont'd)

Table 6. Dedicated Interrupt Instruction Set

Instruction	New Description	Function/Example	I1	H	I0	N	Z	C
HALT	Entering Halt mode		1		0			
IRET	Interrupt routine return	Pop CC, A, X, PC	I1	H	I0	N	Z	C
JRM	Jump if I1:0=11	I1:0=11 ?						
JRNM	Jump if I1:0<>11	I1:0<>11 ?						
POP CC	Pop CC from the Stack	Mem => CC	I1	H	I0	N	Z	C
RIM	Enable interrupt (level 0 set)	Load 10 in I1:0 of CC	1		0			
SIM	Disable interrupt (level 3 set)	Load 11 in I1:0 of CC	1		1			
TRAP	Software trap	Software NMI	1		1			
WFI	Wait for interrupt		1		0			

Note: During the execution of an interrupt routine, the HALT, POPCC, RIM, SIM and WFI instructions change the current software priority up to the next IRET instruction or one of the previously mentioned instructions.

In order not to lose the current software priority level, the RIM, SIM, HALT, WFI and POP CC instructions should never be used in an interrupt routine.

Table 7. Interrupt Mapping

N°	Source Block	Description	Register Label	Priority Order	Exit from HALT	Address Vector
	RESET	Reset	N/A	Highest Priority ↓ Lowest Priority	yes	FFFEh-FFFFh
	TRAP	Software Interrupt			no	FFFCh-FFFDh
0	ICP	FLASH Start programming NMI interrupt			no	FFFAh-FFFBh
1	UART	ISO7816-3 UART Interrupt	UIC		no	FFF8h-FFF9h
2	USB	USB Communication Interrupt	USBISTR		no	FFF6h-FFF7h
3	WAKUP1	External Interrupt Port C			yes	FFF4h-FFF5h
4	WAKUP2	External Interrupt Port A			yes	FFF2h-FFF3h
5	TIM	TBU Timer Interrupt	TBUSR		no	FFF0h-FFF1h
6	CARDDET ¹⁾	Smartcard Insertion/Removal Interrupt ¹⁾	USCUR	yes	FFEEh-FFEFh	
7	ESUSP	End suspend Interrupt	USBISTR	yes	FFECCh-FFEDh	
8	Not used			no	FFEAh-FFEBh	

Note 1: This interrupt can be used to exit from USB suspend mode.

8 POWER SAVING MODES

8.1 INTRODUCTION

To give a large measure of flexibility to the application in terms of power consumption, two main power saving modes are implemented in the ST7.

After a RESET the normal operating mode is selected by default (RUN mode). This mode drives the device (CPU and embedded peripherals) by means of a master clock which is based on the main oscillator frequency.

From Run mode, the different power saving modes may be selected by setting the relevant register bits or by calling the specific ST7 software instruction whose action depends on the oscillator status.

8.2 WAIT MODE

WAIT mode places the MCU in a low power consumption mode by stopping the CPU.

This power saving mode is selected by calling the "WFI" ST7 software instruction.

All peripherals remain active. During WAIT mode, the I bit of the CC register is forced to 0, to enable all interrupts. All other registers and memory remain unchanged. The MCU remains in WAIT mode until an interrupt or Reset occurs, whereupon the Program Counter branches to the starting address of the interrupt or Reset service routine. The MCU will remain in WAIT mode until a Reset or an Interrupt occurs, causing it to wake up.

Refer to Figure 19.

Figure 19. WAIT Mode Flow Chart

POWER SAVING MODES (Cont'd)

8.3 HALT MODE

The HALT mode is the MCU lowest power consumption mode. The HALT mode is entered by executing the HALT instruction. The internal oscillator is then turned off, causing all internal processing to be stopped, including the operation of the on-chip peripherals.

Note: The PLL must be disabled before a HALT instruction.

When entering HALT mode, the I bit in the Condition Code Register is cleared. Thus, any of the external interrupts (ITi or USB end suspend mode), are allowed and if an interrupt occurs, the CPU clock becomes active.

The MCU can exit HALT mode on reception of either an external interrupt on ITi, an end suspend mode interrupt coming from USB peripheral, or a reset. The oscillator is then turned on and a stabilization time is provided before releasing CPU operation. The stabilization time is 512 CPU clock cycles.

After the start up delay, the CPU continues operation by servicing the interrupt which wakes it up or by fetching the reset vector if a reset wakes it up.

Figure 20. HALT Mode Flow Chart

9 I/O PORTS

9.1 Introduction

The I/O ports offer different functional modes:

- transfer of data through digital inputs and outputs and for specific pins:
- alternate signal input/output for the on-chip peripherals.
- external interrupt detection

An I/O port is composed of up to 8 pins. Each pin can be programmed independently as digital input (with or without interrupt generation) or digital output.

9.2 Functional description

Each port is associated to 4 main registers:

- Data Register (DR)
- Data Direction Register (DDR)
- Option Register (OR)
- Pull Up Register (PU)

Each I/O pin may be programmed using the corresponding register bits in DDR register: bit X corresponding to pin X of the port. The same correspondence is used for the DR register.

Table 8. I/O Pin Functions

DDR	MODE
0	Input
1	Output

Input Modes

The input configuration is selected by clearing the corresponding DDR register bit.

In this case, reading the DR register returns the digital value applied to the external I/O pin.

Note 1: All the inputs are triggered by a Schmitt trigger.

Note 2: When switching from input mode to output mode, the DR register should be written first to output the correct value as soon as the port is configured as an output.

Interrupt function

When an I/O is configured in Input with Interrupt, an event on this I/O can generate an external In-

terrupt request to the CPU. The interrupt sensitivity is given independently according to the description mentioned in the ITRFRE interrupt register.

Each pin can independently generate an Interrupt request.

Each external interrupt vector is linked to a dedicated group of I/O port pins (see Interrupts section). If more than one input pin is selected simultaneously as interrupt source, this is logically ORed. For this reason if one of the interrupt pins is tied low, it masks the other ones.

Output Mode

The pin is configured in output mode by setting the corresponding DDR register bit (see Table 7).

In this mode, writing “0” or “1” to the DR register applies this digital value to the I/O pin through the latch. Then reading the DR register returns the previously stored value.

Note: In this mode, the interrupt function is disabled.

Digital Alternate Function

When an on-chip peripheral is configured to use a pin, the alternate function is automatically selected. This alternate function takes priority over standard I/O programming. When the signal is coming from an on-chip peripheral, the I/O pin is automatically configured in output mode (push-pull or open drain according to the peripheral).

When the signal is going to an on-chip peripheral, the I/O pin has to be configured in input mode. In this case, the pin’s state is also digitally readable by addressing the DR register.

Notes:

1. Input pull-up configuration can cause an unexpected value at the input of the alternate peripheral input.
2. When the on-chip peripheral uses a pin as input and output, this pin must be configured as an input (DDR = 0).

Warning: The alternate function must not be activated as long as the pin is configured as input with interrupt, in order to avoid generating spurious interrupts.

I/O PORTS (Cont'd)

9.3 I/O Port Implementation

The hardware implementation on each I/O port depends on the settings in the DDR register and specific feature of the I/O port such as true open drain.

9.3.1 Port A

Table 9. Port A Description

12 ON-CHIP PERIPHERALS

12.1 WATCHDOG TIMER (WDG)

12.1.1 Introduction

The Watchdog timer is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence. The Watchdog circuit generates an MCU reset on expiry of a programmed time period, unless the program refreshes the counter's contents before the T6 bit becomes cleared.

12.1.2 Main Features

- Programmable timer (64 increments of 65536 CPU cycles)
- Programmable reset
- Reset (if watchdog activated) when the T6 bit reaches zero
- Hardware Watchdog selectable by option byte
- Watchdog Reset indicated by status flag

12.1.3 Functional Description

The counter value stored in the CR register (bits T[6:0]), is decremented every 65,536 machine cycles, and the length of the timeout period can be programmed by the user in 64 increments.

If the watchdog is activated (the WDGA bit is set) and when the 7-bit timer (bits T[6:0]) rolls over from 40h to 3Fh (T6 becomes cleared), it initiates a reset cycle pulling low the reset pin for typically 500ns.

The application program must write in the CR register at regular intervals during normal operation to prevent an MCU reset. The value to be stored in the CR register must be between FFh and C0h (see Table 14):

- The WDGA bit is set (watchdog enabled)
- The T6 bit is set to prevent generating an immediate reset
- The T[5:0] bits contain the number of increments which represents the time delay before the watchdog produces a reset.

Table 14. Watchdog Timing ($f_{CPU} = 8\text{ MHz}$)

	CR Register initial value	WDG timeout period (ms)
Max	FFh	524.288
Min	C0h	8.192

Figure 25. Watchdog Block Diagram

WATCHDOG TIMER (Cont'd)

12.1.4 Software Watchdog Option

If Software Watchdog is selected by option byte, the watchdog is disabled following a reset. Once activated it cannot be disabled, except by a reset.

The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).

12.1.5 Hardware Watchdog Option

If Hardware Watchdog is selected by option byte, the watchdog is always active and the WDGA bit in the CR is not used.

12.1.6 Low Power Modes

WAIT Instruction

No effect on Watchdog.

HALT Instruction

Halt mode can be used when the watchdog is enabled. When the oscillator is stopped, the WDG stops counting and is no longer able to generate a reset until the microcontroller receives an external interrupt or a reset.

If an external interrupt is received, the WDG restarts counting after 514 CPU clocks. In the case of the Software Watchdog option, if a reset is generated, the WDG is disabled (reset state).

Recommendations

- Make sure that an external event is available to wake up the microcontroller from Halt mode.
- Before executing the HALT instruction, refresh the WDG counter, to avoid an unexpected WDG reset immediately after waking up the microcontroller.
- When using an external interrupt to wake up the microcontroller, reinitialize the corresponding I/O as Input before executing the HALT instruction. The main reason for this is that the I/O may be wrongly configured due to external interference or by an unforeseen logical condition.
- The opcode for the HALT instruction is 0x8E. To avoid an unexpected HALT instruction due to a program counter failure, it is advised to clear all

occurrences of the data value 0x8E from memory. For example, avoid defining a constant in ROM with the value 0x8E.

- As the HALT instruction clears the I bit in the CC register to allow interrupts, the user may choose to clear all pending interrupt bits before executing the HALT instruction. This avoids entering other peripheral interrupt routines after executing the external interrupt routine corresponding to the wake-up event (reset or external interrupt).

12.1.7 Interrupts

None.

12.1.8 Register Description

CONTROL REGISTER (CR)

Read/Write

Reset Value: 0111 1111 (7Fh)

7							0
WDGA	T6	T5	T4	T3	T2	T1	T0

Bit 7 = **WDGA** Activation bit.

This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.

0: Watchdog disabled

1: Watchdog enabled

Note: This bit is not used if the hardware watchdog option is enabled by option byte.

Bit 6:0 = **T[6:0]** 7-bit timer (MSB to LSB).

These bits contain the decremented value. A reset is produced when it rolls over from 40h to 3Fh (T6 becomes cleared).

12.2 TIME BASE UNIT (TBU)

12.2.1 Introduction

The Timebase unit (TBU) can be used to generate periodic interrupts.

12.2.2 Main Features

- 8-bit upcounter
- Programmable prescaler
- Period between interrupts: max. 8.1ms (at 8 MHz f_{CPU})
- Maskable interrupt

12.2.3 Functional Description

The TBU operates as a free-running upcounter.

When the TCEN bit in the TBUCSR register is set by software, counting starts at the current value of the TBUCV register. The TBUCV register is incremented at the clock rate output from the prescaler selected by programming the PR[2:0] bits in the TBUCSR register.

When the counter rolls over from FFh to 00h, the OVF bit is set and an interrupt request is generated if ITE is set.

The user can write a value at any time in the TBUCV register.

12.2.4 Programming Example

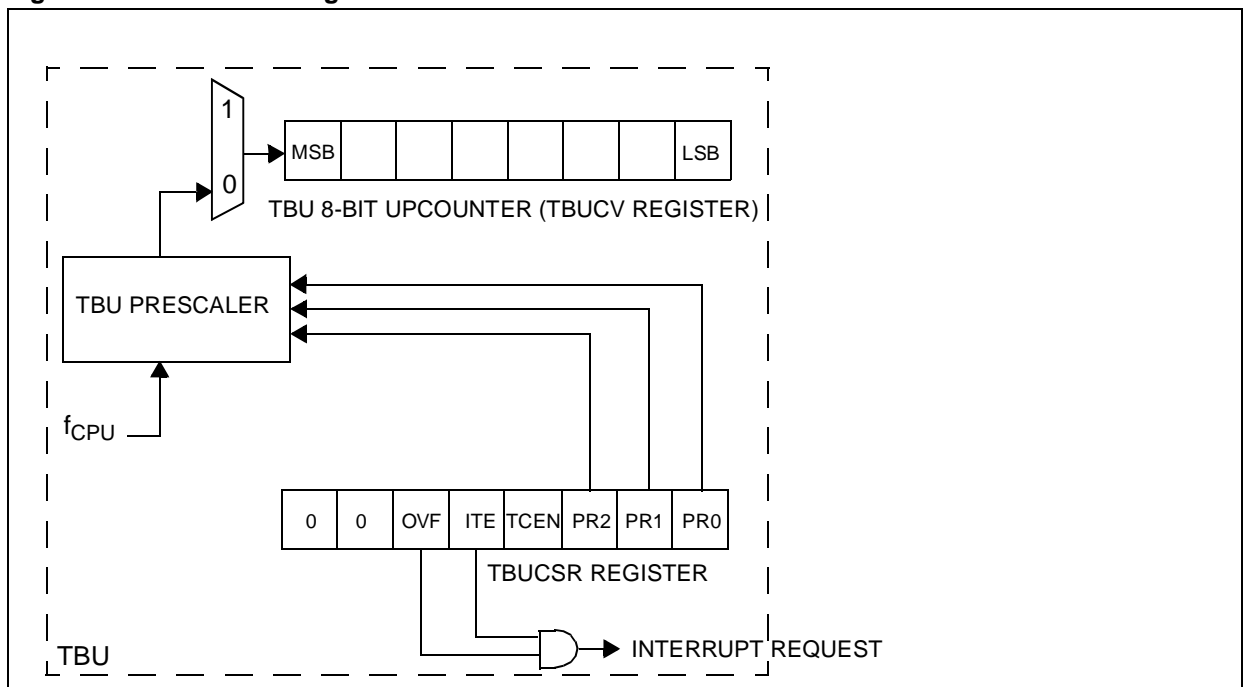

In this example, timer is required to generate an interrupt after a delay of 1 ms.

Assuming that f_{CPU} is 8 MHz and a prescaler division factor of 256 will be programmed using the PR[2:0] bits in the TBUCSR register, 1 ms = 32 TBU timer ticks.

In this case, the initial value to be loaded in the TBUCV must be (256-32) = 224 (E0h).

```
ld A, E0h
ld TBUCV, A ; Initialize counter value
ld A 1Fh ;
ld TBUCSR, A ; Prescaler factor = 256,
; interrupt enable,
; TBU enable
```

Figure 26. TBU Block Diagram

TIMEBASE UNIT (Cont'd)

12.2.5 Low Power Modes

Mode	Description
WAIT	No effect on TBU
HALT	TBU halted.

12.2.6 Interrupts

Interrupt Event	Event Flag	Enable Control Bit	Exit from Wait	Exit from Halt
Counter Overflow Event	OVF	ITE	Yes	No

Note: The OVF interrupt event is connected to an interrupt vector (see Interrupts chapter).

It generates an interrupt if the ITE bit is set in the TBUCSR register and the I-bit in the CC register is reset (RIM instruction).

12.2.7 Register Description

TBU COUNTER VALUE REGISTER (TBU CV)

Read/Write

Reset Value: 0000 0000 (00h)

							7								0
CV7	CV6	CV5	CV4	CV3	CV2	CV1	CV0								

Bits 7:0 = **CV[7:0]** Counter Value

This register contains the 8-bit counter value which can be read and written anytime by software. It is continuously incremented by hardware if TCEN=1.

TBU CONTROL/STATUS REGISTER (TBUCSR)

Read/Write

Reset Value: 0000 0000 (00h)

						7							0
0	0	OVF	ITE	TCEN	PR2	PR1	PR0						

Bits [7:6] = Reserved. Forced by hardware to 0.

Bit 5 = **OVF** Overflow Flag

This bit is set only by hardware, when the counter value rolls over from FFh to 00h. It is cleared by software reading the TBUCSR register. Writing to this bit does not change the bit value.

0: No overflow

1: Counter overflow

Bit 4 = **ITE** Interrupt enabled.

This bit is set and cleared by software.

0: Overflow interrupt disabled

1: Overflow interrupt enabled. An interrupt request is generated when OVF=1.

Bit 3 = **TCEN** TBU Enable.

This bit is set and cleared by software.

0: TBU counter is frozen and the prescaler is reset.

1: TBU counter and prescaler running.

Bits 2:0 = **PR[2:0]** Prescaler Selection

These bits are set and cleared by software to select the prescaling factor.

PR2	PR1	PR0	Prescaler Division Factor
0	0	0	2
0	0	1	4
0	1	0	8
0	1	1	16
1	0	0	32
1	0	1	64
1	1	0	128
1	1	1	256

12.3 USB INTERFACE (USB)

12.3.1 Introduction

The USB Interface implements a full-speed function interface between the USB and the ST7 microcontroller. It is a highly integrated circuit which includes the transceiver, 3.3 voltage regulator, SIE and USB Data Buffer interface. No external components are needed apart from the external pull-up on USBDP for full speed recognition by the USB host.

12.3.2 Main Features

- USB Specification Version 1.1 Compliant
- Supports Full-Speed USB Protocol
- Seven Endpoints (including default endpoint)
- CRC generation/checking, NRZI encoding/decoding and bit-stuffing
- USB Suspend/Resume operations
- On-Chip 3.3V Regulator
- On-Chip USB Transceiver

12.3.3 Functional Description

The block diagram in Figure 27, gives an overview of the USB interface hardware.

For general information on the USB, refer to the “Universal Serial Bus Specifications” document available at <http://www.usb.org>.

Serial Interface Engine

The SIE (Serial Interface Engine) interfaces with the USB, via the transceiver.

The SIE processes tokens, handles data transmission/reception, and handshaking as required by the USB standard. It also performs frame formatting, including CRC generation and checking.

Endpoints

The Endpoint registers indicate if the microcontroller is ready to transmit/receive, and how many bytes need to be transmitted.

Data Transfer to/from USB Data Buffer Memory

When a token for a valid Endpoint is recognized by the USB interface, the related data transfer takes place to/from the USB data buffer. At the end of the transaction, an interrupt is generated.

Interrupts

By reading the Interrupt Status register, application software can know which USB event has occurred.

Figure 27. USB Block Diagram

USB INTERFACE (Cont'd)**USB Endpoint RAM Buffers**

There are seven Endpoints including one bidirectional control Endpoint (Endpoint 0), five IN Endpoints (Endpoint 1, 2, 3, 4, 5) and one OUT endpoint (Endpoint 2).

Endpoint 0 is 2 x 8 bytes in size, Endpoint 1, 3, 4, and Endpoint 5 are 8 bytes in size and Endpoint 2 is 2 x 64 bytes in size .

Figure 28. Endpoint Buffer Size

Endpoint 0 Buffer OUT	8 Bytes
Endpoint 0 Buffer IN	8 Bytes
Endpoint 1 Buffer IN	8 Bytes
Endpoint 2 Buffer OUT	64 Bytes
Endpoint 2 Buffer IN	64 Bytes
Endpoint 3 Buffer IN	8 Bytes
Endpoint 4 Buffer IN	8 Bytes
Endpoint 5 Buffer IN	8 Bytes

USB INTERFACE (Cont'd)

12.3.4 Register Description

INTERRUPT STATUS REGISTER (USBISTR)

Read/Write

Reset Value: 0000 0000 (00h)

7	0							0
CTR	0	SOVR	ERROR	SUSP	ESUSP	RESET	SOF	

These bits cannot be set by software. When an interrupt occurs these bits are set by hardware. Software must read them to determine the interrupt type and clear them after servicing.

Note: The CTR bit (which is an OR of all the endpoint CTR flags) cannot be cleared directly, only by clearing the CTR flags in the Endpoint registers.

Bit 7 = **CTR** *Correct Transfer.*

This bit is set by hardware when a correct transfer operation is performed. This bit is an OR of all CTR flags (CTR0 in the EP0R register and CTR_RX and CTR_TX in the EPnRXR and EPnTXR registers). By looking in the USBSR register, the type of transfer can be determined from the PID[1:0] bits for Endpoint 0. For the other Endpoints, the Endpoint number on which the transfer was made is identified by the EP[1:0] bits and the type of transfer by the IN/OUT bit.

0: No Correct Transfer detected
1: Correct Transfer detected

Note: A transfer where the device sent a NAK or STALL handshake is considered not correct (the host only sends ACK handshakes). A transfer is considered correct if there are no errors in the PID and CRC fields, if the DATA0/DATA1 PID is sent as expected, if there were no data overruns, bit stuffing or framing errors.

Bit 6 = Reserved, forced by hardware to 0.

Bit 5 = **SOVR** *Setup Overrun.*

This bit is set by hardware when a correct Setup transfer operation is performed while the software is servicing an interrupt which occurred on the same Endpoint (CTR0 bit in the EP0R register is still set when SETUP correct transfer occurs).

0: No SETUP overrun detected
1: SETUP overrun detected

When this event occurs, the USBSR register is not updated because the only source of the SOVR

event is the SETUP token reception on the Control Endpoint (EP0).

Bit 4 = **ERR** *Error.*

This bit is set by hardware whenever one of the errors listed below has occurred:

0: No error detected
1: Timeout, CRC, bit stuffing, nonstandard framing or buffer overrun error detected

Note: Refer to the ERR[2:0] bits in the USBSR register to determine the error type.

Bit 3 = **SUSP** *Suspend mode request.*

This bit is set by hardware when a constant idle state is present on the bus line for more than 3 ms, indicating a suspend mode request from the USB.

The suspend request check is active immediately after each USB reset event and is disabled by hardware when suspend mode is forced (FSUSP bit in the USBCTLR register) until the end of resume sequence.

Bit 2 = **ESUSP** *End Suspend mode.*

This bit is set by hardware when, during suspend mode, activity is detected that wakes the USB interface up from suspend mode.

This interrupt is serviced by a specific vector, in order to wake up the ST7 from HALT mode.

0: No End Suspend detected
1: End Suspend detected

Bit 1 = **RESET** *USB reset.*

This bit is set by hardware when the USB reset sequence is detected on the bus.

0: No USB reset signal detected
1: USB reset signal detected

Note: The DADDR, EP0R, EP1RXR, EP1TXR, EP2RXR and EP2TXR registers are reset by a USB reset.

Bit 0 = **SOF** *Start of frame.*

This bit is set by hardware when a SOF token is received on the USB.

0: No SOF received
1: SOF received

Note: To avoid spurious clearing of some bits, it is recommended to clear them using a load instruction where all bits which must not be altered are set, and all bits to be cleared are reset. Avoid read-modify-write instructions like AND, XOR...

USB INTERFACE (Cont'd)**INTERRUPT MASK REGISTER (USBIMR)**

Read/Write

Reset Value: 0000 0000 (00h)

7							0
CTRM	0	SOVR M	ERRM	SUSP M	ESUSP M	RESET M	SOFM

These bits are mask bits for all the interrupt condition bits included in the USBISTR register. Whenever one of the USBIMR bits is set, if the corresponding USBISTR bit is set, and the I- bit in the CC register is cleared, an interrupt request is generated. For an explanation of each bit, please refer to the description of the USBISTR register.

CONTROL REGISTER (USBCTLR)

Read/Write

Reset value: 0000 0110 (06h)

7							0
RSM	USB_ RST	0	0	RESU ME	PDWN	FSUSP	FRES

Bit 7 = RSM Resume Detected

This bit shows when a resume sequence has started on the USB port, requesting the USB interface to wake-up from suspend state. It can be used to determine the cause of an ESUSP event.

0: No resume sequence detected on USB

1: Resume sequence detected on USB

Bit 6 = USB_RST USB Reset detected.

This bit shows that a reset sequence has started on the USB. It can be used to determine the cause of an ESUSP event (Reset sequence).

0: No reset sequence detected on USB

1: Reset sequence detected on USB

Bits [5:4] = Reserved, forced by hardware to 0.

Bit 3 = RESUME Resume.

This bit is set by software to wake-up the Host when the ST7 is in suspend mode.

0: Resume signal not forced

1: Resume signal forced on the USB bus.

Software should clear this bit after the appropriate delay.

Bit 2 = PDWN Power down.

This bit is set by software to turn off the 3.3V on-chip voltage regulator that supplies the external pull-up resistor and the transceiver.

0: Voltage regulator on

1: Voltage regulator off

Note: After turning on the voltage regulator, software should allow at least 3 μ s for stabilisation of the power supply before using the USB interface.

Bit 1 = FSUSP Force suspend mode.

This bit is set by software to enter Suspend mode. The ST7 should also be put in Halt mode to reduce power consumption.

0: Suspend mode inactive

1: Suspend mode active

When the hardware detects USB activity, it resets this bit (it can also be reset by software).

Bit 0 = FRES Force reset.

This bit is set by software to force a reset of the USB interface, just as if a RESET sequence came from the USB.

0: Reset not forced

1: USB interface reset forced.

The USB is held in RESET state until software clears this bit, at which point a "USB-RESET" interrupt will be generated if enabled.

USB INTERFACE (Cont'd)

DEVICE ADDRESS REGISTER (DADDR)

Read/Write

Reset Value: 0000 0000 (00h)

7							0
0	ADD6	ADD5	ADD4	ADD3	ADD2	ADD1	ADD0

Bit 7 = Reserved, forced by hardware to 0.

Bits 6:0 = **ADD[6:0]** *Device address, 7 bits.*

Software must write into this register the address sent by the host during enumeration.

Note: This register is also reset when a USB reset is received or forced through bit FRES in the USBCTLR register.

USB STATUS REGISTER (USBSR)

Read only

Reset Value: 0000 0000 (00h)

7							0
PID1	PID0	IN/ OUT	0	0	EP2	EP1	EP0

Bits 7:6 = **PID[1:0]** *Token PID bits 1 & 0 for Endpoint 0 Control.*

USB token PIDs are encoded in four bits. PID[1:0] correspond to the most significant bits of the PID field of the last token PID received by Endpoint 0.

Note: The least significant PID bits have a fixed value of 01.

When a CTR interrupt occurs on Endpoint 0 (see register USBISTR) the software should read the PID[1:0] bits to retrieve the PID name of the token received.

The USB specification defines PID bits as:

PID1	PID0	PID Name
0	0	OUT
1	0	IN
1	1	SETUP

Bit 5 = **IN/OUT** *Last transaction direction for Endpoint 1, 2, 3, 4 or 5.*

This bit is set by hardware when a CTR interrupt occurs on Endpoint 1, 2, 3, 4 or 5.

0: OUT transaction

1: IN transaction

Bits 4:3 = Reserved, forced by hardware to 0.

Bits 2:0 = **EP[2:0]** *Endpoint number.*

These bits identify the endpoint which required attention.

000 = Endpoint 0

001 = Endpoint 1

010 = Endpoint 2

011 = Endpoint 3

100 = Endpoint 4

101 = Endpoint 5

ERROR STATUS REGISTER (ERRSR)

Read only

Reset Value: 0000 0000 (00h)

7						0	
0	0	0	0	0	ERR2	ERR1	ERR0

Bits 7:3 = Reserved, forced by hardware to 0.

Bits 2:0 = **ERR[2:0]** *Error type.*

These bits identify the type of error which occurred.

ERR2	ERR1	ERR0	Meaning
0	0	0	No error
0	0	1	Bitstuffing error
0	1	0	CRC error
0	1	1	EOP error (unexpected end of packet or SE0 not followed by J-state)
1	0	0	PID error (PID encoding error, unexpected or unknown PID)
1	0	1	Memory over / underrun (memory controller has not answered in time to a memory data request)
1	1	1	Other error (wrong packet, timeout error)

Note: these bits are set by hardware when an error interrupt occurs and are reset automatically when the error bit (USBISTR bit 4) is cleared by software.

USB INTERFACE (Cont'd)**ENDPOINT 0 REGISTER (EP0R)**

Read/Write

Reset value: 0000 0000(00h)

7							0
CTR0	D T O G _ T X	S T A T _ T X 1	S T A T _ T X 0	0	D T O G _ R X	S T A T _ R X 1	S T A T _ R X 0

This register is used for controlling Endpoint 0. Bits 6:4 and bits 2:0 are also reset by a USB reset, either received from the USB or forced through the FRES bit in USBCTLR.

Bit 7 = **CTR0** *Correct Transfer*.

This bit is set by hardware when a correct transfer operation is performed on Endpoint 0. This bit must be cleared after the corresponding interrupt has been serviced.

0: No CTR on Endpoint 0

1: Correct transfer on Endpoint 0

Bit 6 = **DTOG_TX** *Data Toggle, for transmission transfers*.

It contains the required value of the toggle bit (0=DATA0, 1=DATA1) for the next transmitted data packet. This bit is set by hardware on reception of a SETUP PID. DTOG_TX toggles only when the transmitter has received the ACK signal from the USB host. DTOG_TX and also DTOG_RX are normally updated by hardware, on receipt of a relevant PID. They can be also written by the user, both for testing purposes and to force a specific (DATA0 or DATA1) token.

Bits 5:4 = **STAT_TX [1:0]** *Status bits, for transmission transfers*.

These bits contain the information about the endpoint status, which are listed below

Table 15. Transmission Status Encoding

STAT_TX1	STAT_TX0	Meaning
0	0	DISABLED: no function can be executed on this endpoint and messages related to this endpoint are ignored.
0	1	STALL: the endpoint is stalled and all transmission requests result in a STALL handshake.
1	0	NAK: the endpoint is NAKed and all transmission requests result in a NAK handshake.
1	1	VALID: this endpoint is enabled (if an address match occurs, the USB interface handles the transaction).

These bits are written by software. Hardware sets the STAT_TX and STAT_RX bits to NAK when a correct transfer has occurred (CTR=1) addressed to this endpoint; this allows software to prepare the next set of data to be transmitted.

Bit 3 = Reserved, forced by hardware to 0.

Bit 2 = **DTOG_RX** *Data Toggle, for reception transfers*.

It contains the expected value of the toggle bit (0=DATA0, 1=DATA1) for the next data packet. This bit is cleared by hardware in the first stage (Setup Stage) of a control transfer (SETUP transactions start always with DATA0 PID). The receiver toggles DTOG_RX only if it receives a correct data packet and the packet's data PID matches the receiver sequence bit.

USB INTERFACE (Cont'd)

Bits 1:0 = **STAT_RX [1:0]** *Status bits, for reception transfers.*

These bits contain the information about the endpoint status, which are listed below:

Table 16. Reception Status Encoding

STAT_RX1	STAT_RX0	Meaning
0	0	DISABLED: no function can be executed on this endpoint and messages related to this endpoint are ignored.
0	1	STALL: the endpoint is stalled and all reception requests result in a STALL handshake.
1	0	NAK: the endpoint is NAKed and all reception requests result in a NAK handshake.
1	1	VALID: this endpoint is enabled (if an address match occurs, the USB interface handles the transaction).

These bits are written by software. Hardware sets the STAT_RX and STAT_TX bits to NAK when a correct transfer has occurred (CTR=1) addressed to this endpoint, so the software has the time to examine the received data before acknowledging a new transaction.

Note 1:

If a SETUP transaction is received while the status is different from DISABLED, it is acknowledged and the two directional status bits are set to NAK by hardware.

Note 2:

When a STALL is answered by the USB device, the two directional status bits are set to STALL by hardware.

ENDPOINT TRANSMISSION REGISTER (EP1TXR, EP2TXR, EP3TXR, EP4TXR, EP5TXR)

Read/Write

Reset value: 0000 0000 (00h)

7					0		
0	0	0	0	CTR_TX	D_TOG_TX	STAT_TX1	STAT_TX0

This register is used for controlling Endpoint 1, 2, 3, 4 or 5 transmission. Bits 2:0 are also reset by a

USB reset, either received from the USB or forced through the FRES bit in the USBCTLR register.

Bits [7:4] = Reserved, forced by hardware to 0.

Bit 3 = **CTR_TX** *Correct Transmission Transfer.*

This bit is set by hardware when a correct transfer operation is performed in transmission. This bit must be cleared after the corresponding interrupt has been serviced.

0: No CTR in transmission on Endpoint 1, 2, 3, 4 or 5

1: Correct transfer in transmission on Endpoint 1, 2, 3, 4 or 5

Bit 2 = **D_TOG_TX** *Data Toggle, for transmission transfers.*

This bit contains the required value of the toggle bit (0=DATA0, 1=DATA1) for the next data packet. D_TOG_TX toggles only when the transmitter has received the ACK signal from the USB host. D_TOG_TX and D_TOG_RX are normally updated by hardware, at the receipt of a relevant PID. They can be also written by the user, both for testing purposes and to force a specific (DATA0 or DATA1) token.

Bits [1:0] = **STAT_TX [1:0]** *Status bits, for transmission transfers.*

These bits contain the information about the endpoint status, which is listed below

Table 17. Transmission Status Encoding

STAT_TX1	STAT_TX0	Meaning
0	0	DISABLED: transmission transfers cannot be executed.
0	1	STALL: the endpoint is stalled and all transmission requests result in a STALL handshake.
1	0	NAK: the endpoint is naked and all transmission requests result in a NAK handshake.
1	1	VALID: this endpoint is enabled for transmission.

These bits are written by software, but hardware sets the STAT_TX bits to NAK when a correct transfer has occurred (CTR=1) addressed to this endpoint. This allows software to prepare the next set of data to be transmitted.

USB INTERFACE (Cont'd)**ENDPOINT 2 RECEPTION REGISTER (EP2RXR)**

Read/Write

Reset value: 0000 0000 (00h)

7					0		
0	0	0	0	CTR_ RX	D TOG _RX	STAT_ RX1	STAT_ RX0

This register is used for controlling Endpoint 2 reception. Bits 2:0 are also reset by a USB reset, either received from the USB or forced through the FRES bit in the USBCTLR register.

Bits [7:4] = Reserved, forced by hardware to 0.

Bit 3 = **CTR_RX** *Reception Correct Transfer*. This bit is set by hardware when a correct transfer operation is performed in reception. This bit must be cleared after that the corresponding interrupt has been serviced.

Bit 2 = **DTOG_RX** *Data Toggle, for reception transfers*.

It contains the expected value of the toggle bit (0=DATA0, 1=DATA1) for the next data packet.

The receiver toggles DTOG_RX only if it receives a correct data packet and the packet's data PID matches the receiver sequence bit.

Bits [1:0] = **STAT_RX [1:0]** *Status bits, for reception transfers*.

These bits contain the information about the endpoint status, which is listed below:

Table 18. Reception Status Encoding

STAT_RX1	STAT_RX0	Meaning
0	0	DISABLED: reception transfers cannot be executed.
0	1	STALL: the endpoint is stalled and all reception requests result in a STALL handshake.
1	0	NAK: the endpoint is naked and all reception requests result in a NAK handshake.
1	1	VALID: this endpoint is enabled for reception.

These bits are written by software, but hardware sets the STAT_RX bits to NAK when a correct transfer has occurred (CTR=1) addressed to this endpoint, so the software has the time to examine the received data before acknowledging a new transaction.

USB INTERFACE (Cont'd)

RECEPTION COUNTER REGISTER (CNT0RXR)

Read/Write

Reset Value: 0000 0000 (00h)

This register contains the allocated buffer size for endpoint 0 reception, setting the maximum number of bytes the related endpoint can receive with the next OUT or SETUP transaction. At the end of a reception, the value of this register is the max size decremented by the number of bytes received (to determine the number of bytes received, the software must subtract the content of this register from the allocated buffer size).

TRANSMISSION COUNTER REGISTER (CNT0TXR, CNT1TXR, CNT3TXR, CNT4TXR, CNT5TXR)

Read/Write

Reset Value 0000 0000 (00h)

This register contains the number of bytes to be transmitted by Endpoint 0, 1, 3, 4 or 5 at the next IN token addressed to it.

RECEPTION COUNTER REGISTER (CNT2RXR)

Read/Write

Reset Value: 0000 0000 (00h)

This register contains the allocated buffer size for endpoint 2 reception, setting the maximum number of bytes the related endpoint can receive with the next OUT transaction. At the end of a reception, the value of this register is the max size decremented by the number of bytes received (to determine the number of bytes received, the software must subtract the content of this register from the allocated buffer size).

TRANSMISSION COUNTER REGISTER (CNT2TXR)

Read/Write

Reset Value 0000 0000 (00h)

This register contains the number of bytes to be transmitted by Endpoint 2 at the next IN token addressed to it.

USB INTERFACE (Cont'd)

SMARTCARD INTERFACE (Cont'd)

12.4.3.1 Power Supply Management

Smartcard Power Supply Selection

The Smartcard interface consists of a power supply output on the CRDVCC pin and a set of card interface I/Os which are powered by the same rail.

The card voltage (CRDVCC) is user programmable via the VCARD [1:0] bits in the CRDCR register (refer to the Smartcard Interface section).

Four voltage values can be selected: 5V, 3 V, 1.8 V or 0V.

Current Overload Detection and Card Removal

For each voltage, when an overload current is detected (refer to Section 12.4 on page 55), or when a card is removed, the CRDVCC power supply output is directly connected to ground.

12.4.3.2 I/O Driving Modes

Smartcard I/Os are driven in two principal modes:

- UART mode (i.e. when the UART bit of the CRDCR register is set)
- Manual mode, driven directly by software using the Smartcard Contact register (i.e. when the UART bit of the CRDCR register is reset).

Card power-on activation must be driven by software.

Card deactivation is handled automatically by the Power-off functional state machine hardware.

12.4.3.3 UART Mode

Two registers are connected to the UART shift register: CRDTXB for transmission and CRDRXB for reception. They act as buffers to off-load the CPU.

A parity checker and generator is coupled to the shifter.

Character repetition and retry are supported.

The UART is in reception mode by default and switches automatically to transmission mode when a byte is written in the buffer.

Priority is given to transmission.

Elementary Time Unit Counter

This 11-bit counter controls the working frequency of the UART. The operating frequency of the clock is the same as the card clock frequency (i.e. 4 MHz).

A compensation mode can be activated via the COMP bit of the CRDETU1 register to allow a frequency granularity down to a half-etu.

Note: The decimal value is limited to a half clock cycle. The bit duration is not fixed. It alternates between n clock cycles and $n-1$ clock cycles, where n is the value to be written in the CRDETU register. The character duration (10 bits) is also equal to $10 \cdot (n - \frac{1}{2})$ clock cycles. This is precise enough to obtain the character duration specified by the ISO7816-3 standard.

For example, if $F=372$ and $D=32$ (F being the clock rate conversion factor and D the baud rate adjustment), then $etu = 11.625$ clock cycles.

To achieve this clock rate, compensation mode must be activated and the etu duration must be programmed to 12 clock cycles.

The result will be an average character duration of 11.5 clock cycles (for 10 bits).

See Figure 30.

Guardtime counter

The guardtime counter is a 9-bit counter which manages the character frame. It controls the duration between two consecutive characters in transmission.

It is incremented at the etu rate.

No guardtime is inserted for the first character transmitted.

The guardtime between the last byte received from the card and the next byte transmitted by the reader must be handled by software.

Figure 30. Compensation Mode

SMARTCARD INTERFACE (Cont'd)

Waiting Time Counter

The Waiting Time counter is a 24-bit counter used to generate a timeout signal.

The elementary time unit counter acts as a prescaler to the Waiting Time counter which is incremented at the etu rate.

The Waiting Time Counter can be used in both UART mode and Manual mode and acts in different ways depending on the selected mode.

The CRDWT2, CRDWT1 and CRDWT0 are load registers only, the counter itself is not directly accessible.

UART Mode

The load conditions are either:

– A Start bit is detected while UART bit = 1 and the WTEN bit = 1.

or

– A write access to the CRDWT2 register is performed while the UART bit = 1 and the WTEN bit = 0. In this case, the Waiting Time counter can be used as a general purpose timer.

In UART mode, if the WTEN bit of the CRDCR register is set, the counter is loaded automatically on start bit detection. Software can change the time out value on-the-fly by writing to the CRDWT registers. For example, in T=1 mode, software must load the Block Waiting Time (BWT) time-out in the CRDWT registers before the start

bit of the last transmitted character.

Then, after transmission of this last character, signalled by the TXC interrupt, software must write the CWT value (Character Waiting Time) in the CRDWT registers. See example in Figure 31.

Manual mode

The load conditions are:

– A write access to the CRDWT2 register is performed while the UART bit = 0 and the WTEN bit = 0

In Manual mode, if the WTEN bit of the CRDCR register is reset, the timer acts as a general purpose timer. The timer is loaded when a write access to the CRDWT2 register occurs. The timer starts when the WTEN bit = 1.

12.4.3.4 Interrupt generator

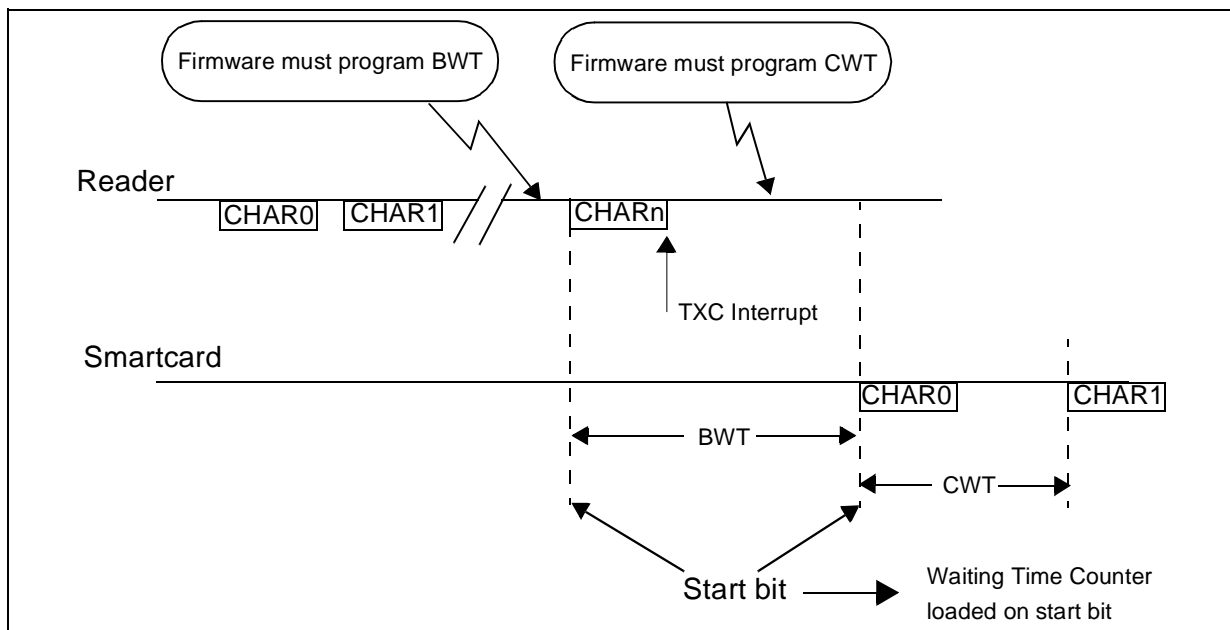

The Smartcard Interface has 2 interrupt vectors:

- Card Insertion/Removal Interrupt
- CRD Interrupt

The CRD interrupt is cleared when software reads the CRDIPR register. The Card Insertion/Removal is an external interrupt and is cleared automatically by hardware at the end of the interrupt service routine (IRET instruction).

If an interrupt occurs while the CRDIPR register is being read, the corresponding bit will be set by hardware after the read access is done.

Figure 31. Waiting Time Counter Example

SMARTCARD INTERFACE (Cont'd)

12.4.3.5 Card detection mechanism

The CRDDET bit in the CRDCR Register indicates if the card presence detector (card switch) is open or closed when a card is inserted. When the CRDIRF bit of the CRDSR is set, it indicates that a card is present.

To be able to power-on the smartcard, card presence is mandatory. Removing the smartcard will automatically start the ISO7816-3 card deactivation sequence (see Section 12.4.3.6).

There is no hardware debouncing: The CRDIRF bit changes whenever the level on the CRDDET pin changes. The card switch can generate an interrupt which can be used to wake up the device from suspend mode and for software debouncing.

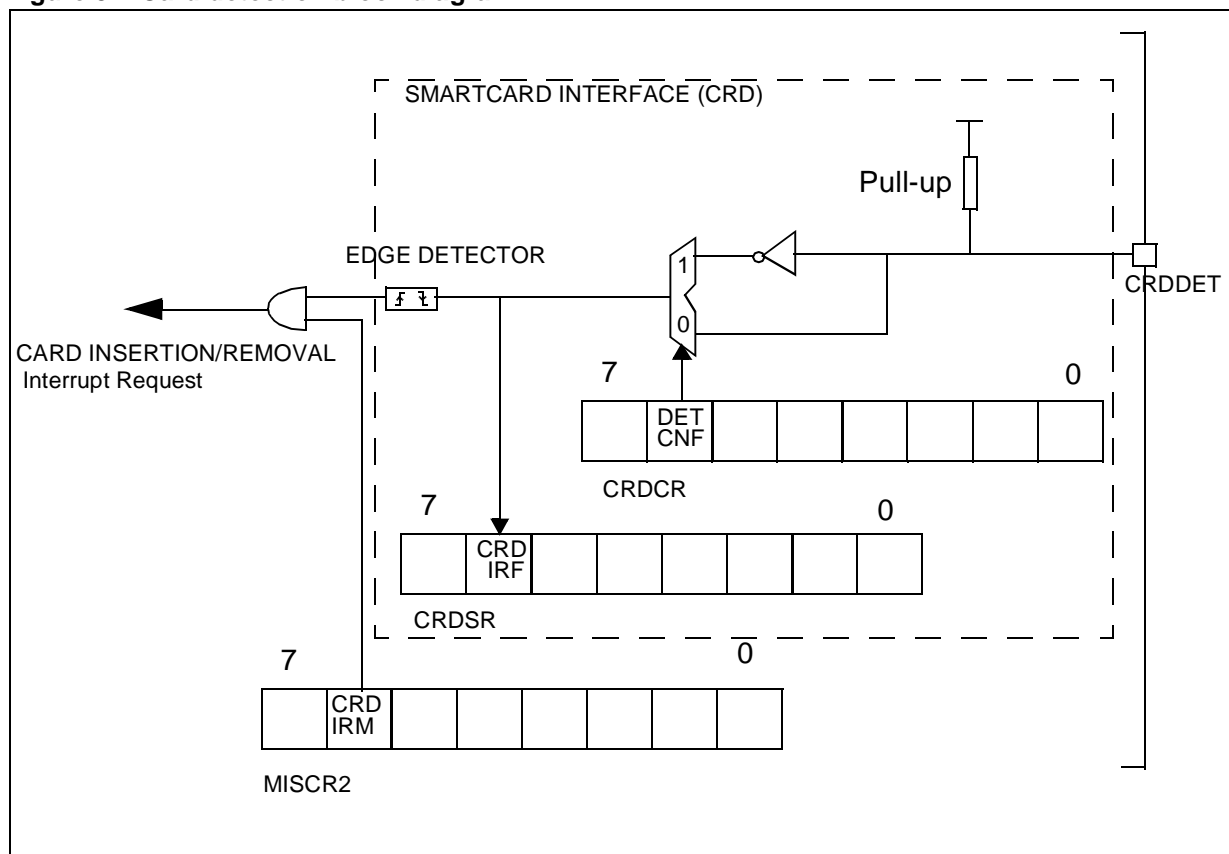

Three different cases can occur:

- The microcontroller is in run mode, waiting for card insertion:
Card insertion generates an interrupt and the

CRDIRF bit in the CRDSR register is set. Debouncing is managed by software. After the time required for debouncing, if the CRDIRF bit is set, the CRDVCC bit in the CRDCR register is set by software to apply the selected voltage to the CRDVCC pin

- The microcontroller is in suspend mode and a card is inserted:
The ST7 is woken up by the interrupt. The card insertion is then handled in the same way as in the previous case.
- The card is removed:
 - The CRDIRF bit is reset without hardware debouncing
 - A Card Insertion/Removal interrupt is generated, (if enabled by the CRDIRM bit in the MISCR2 register)
 - The CRDVCC bit is immediately reset by hardware, starting the card deactivation sequence.

Figure 32. Card detection block diagram

SMARTCARD INTERFACE (Cont'd)

12.4.3.6 Card Deactivation Sequence

This sequence can be activated in two different ways:

- Automatically as soon as the card presence detector detects a card removal (via the CRDIRF bit in the CRDSR register, refer to Section 12.4.3.5).
- By software, writing the CRDVCC bit in the CRDCCR register, for example:
 - If there is a smartcard current overflow (i.e. when the IOVFF bit in the CRDSR register is set)
 - If the voltage is not within the specified range (i.e. when the VCARDOK bit in the CRDSR register is cleared), but software must clear the CRDVCC bit in the CRDCCR register to start the deactivation sequence.

When the CRDVCC bit is cleared, this starts the deactivation sequence. CRDCLK, CRDIO, CRDC4 and CRDC8 pins are then deactivated as shown in Figure 33:

Figure 33. Card deactivation sequence

SMARTCARD INTERFACE (Cont'd)

12.4.4 Register Description

SMARTCARD INTERFACE CONTROL REGISTER (CRDCR)

Read/Write

Reset Value: 0000 0000 (00h)

7							0
CRD RST	CRD DET	VCAR D 1	VCAR D 0	U ART	WT EN	C REP	CO NV

Bit 7 = **CRDRST** *Smartcard Interface Reset.*

This bit is set by software to reset the UART of the Smartcard interface.

- 0: No Smartcard UART Reset
- 1: Smartcard UART Reset

Bit 6 = **CRDDET** *Card Presence Detector.*

This bit is set and cleared by software to configure the card presence detector switch.

- 0: Switch open if no card is present
- 1: Switch closed if no card is present

Bits [5:4] = **VCARD[1:0]** *Card voltage selection.*

These bits select the card voltage.

Bit 1	Bit 0	Vcard
0	0	0V
0	1	1.8V
1	0	3V
1	1	5V

Bit 3 = **UART** *UART Mode Selection.*

This bit is set and cleared by software to select UART or manual mode.

- 0: CRDIO pin is a copy of the CRDIO bit in the CRDCCR register (Manual mode).
- 1: CRDIO pin is the output of the smartcard UART (UART mode).

Caution: Before switching from Manual mode to UART mode, software must set the CRDIO bit in the CRDCCR register.

Bit 2 = **WTEN** *Waiting Time Counter enable.*

0: Waiting Time counter stopped. While WTEN = 0, a write access to the CRDWT2 register loads the Waiting time counter with the load value held in the CRDWT0, CRDWT1 and CRDWT2 registers.

1: Start counter. In UART mode, the counter is automatically reloaded on start bit detection.

Bit 1 = **CREP** *Automatic character repetition in case of parity error.*

0: In reception mode: no parity error signal indication (no retry on parity error).

In transmission mode: no error signal processing. No retransmission of a refused character on parity error.

1: Automatic parity management:

In transmission mode: up to 4 character repetitions on parity error.

In reception mode: up to 4 retries are made on parity error.

The PARF parity error flag is set by hardware if a parity error is detected.

If the transmitted character is refused, the PARF bit is set (but the TXCF bit is reset) and an interrupt is generated if the PARM bit is set.

Note: If CREP=1, the PARF flag is set at the 5th error (after 4 character repetitions or 4 retries).

If CREP=0, the PARF bit is set after the first parity error.

Bit 0 = **CONV** *ISO convention selection.*

0: Direct convention, the B0 bit (LSB) is sent first, a '1' is a level 1 on the Card I/O pin, the parity bit is added after the B7 bit.

1: Inverse convention, the B7 bit (MSB) is sent first, a '1' is a level 0 on Card I/O pin, the parity bit is added after the B0 bit.

Note: To detect the convention used by any card, apply the following rule. If a card uses the convention selected by the reader, an RXC event occurs at answer to reset. Otherwise a parity error also occurs.

SMARTCARD INTERFACE (Cont'd)**SMARTCARD INTERFACE STATUS REGISTER (CRDSR)**

Read only (Read/Write on some bits)

Reset Value: 1000 0000 (80h)

7							0
TXBE F	CRD IRF	IOVF	VCARD OK	WTF	TXC F	RXC F	PAR F

Bit 7 = **TxBEF** *Transmit Buffer Empty Flag.*

- Read only

0: Transmit buffer is not empty

1: Transmit buffer is empty

Bit 6 = **CRDIRF** *Card Insertion/Removal Flag.*

- Read only

0: No card is present

1: A card is present

Bit 5 = **IOVF** *Card Overload Current Flag.*

- Read only

0: No card overload current

1: Card overload current

Bit 4 = **VCARDOK** *Card voltage status Flag.*

- Read only

0: The card voltage is not in the specified range

1: The card voltage is within the specified range

Bit 3 = **WTF** *Waiting Time Counter overflow Flag.*

- Read only

0: The WT Counter has not reached its maximum value

1: The WT Counter has reached its maximum value

Bit 2 = **TXCF** *Transmitted character Flag.*

- Read/Write

This bit is set by hardware and cleared by software.

0: No character transmitted

1: A character has been transmitted

Bit 1 = **RXCF** *Received character Flag.*

- Read only

This bit is set by hardware and cleared by hardware when the CRDRXB buffer is read.

0: No character received

1: A character has been received

Bit 0 = **PARF** *Parity Error Flag.*

- Read/Write

This bit is set by hardware and cleared by software.

0: No parity error

1: Parity error

Note: When a character is received, the RXCF bit is always set. When a character is received with a parity error, the PARF bit is also set.

SMARTCARD INTERFACE (Cont'd)

SMARTCARD CONTACT CONTROL REGISTER (CRDCCR)

Read/Write

Reset Value: 00xx xx00 (xxh)

7							0
CLK SEL	-	CRD C8	CRD C4	CRD IO	CRD CLK	CRD RST	CRD VCC

Note: To modify the content of this register, the LD instruction must be used (do not use the BSET and BRES instructions).

Bit 7 = **CLKSEL** Card clock selection.

This bit is set and cleared by software.

0: The signal on the CRDCLK pin is a copy of the CRDCLK bit.

1: The signal on the CRDCLK pin is a 4MHz frequency clock.

Note: To start the clock at a known level, the CRDCLK bit should be changed before the CLKSEL bit.

Bit 6 = Reserved, must be kept cleared.

Bit 5 = **CRDC8** CRDC8 pin control.

Reading this bit returns the value present on the CRDC8 pin. Writing this bit outputs the bit value on the pin.

Bit 4 = **CRDC4** CRDC4 pin control

Reading this bit returns the value present on the CRDC4 pin. Writing this bit outputs the bit value on the pin.

Bit 3 = **CRDIO** CRDIO pin control.

This bit is active only if the UART bit in the CRDCR Register is reset. Reading this bit returns the value present on the CRDIO pin.

If the UART bit is reset:

- Writing "0" forces a low level on the CRDIO pin
- Writing "1" forces the CRDIO pin to open drain Hi-Z.

Bit 2 = **CRDCLK** CRDCLK pin control

This bit is active only if the CLKSEL bit of the CRDCCR register is reset. Reading this bit returns the value present in the register (not the CRDCLK pin value).

When the CLKSEL bit is reset:

0: Level 0 to be applied on CRDCLK pin.

1: Level 1 to be applied on CRDCLK pin.

Note: To ensure that the clock stops at a given value, write the desired value in the CRDCLK bit prior to changing the CLKSEL bit from 1 to 0.

Bit 1 = **CRDRST** CRDRST pin control.

Reading this bit returns the value present on the CRDRST pin. Writing this bit outputs the bit value on the pin.

Bit 0 = **CRDVCC** CRDVCC Pin Control.

This bit is set and cleared by software and forced to 0 by hardware when no card is present (CRDIRF bit=0).

0: No voltage to be applied on the CRDVCC pin.

1: The selected voltage must be applied on the CRDVCC pin.

Figure 37. Smartcard I/O Pin Structure

SMARTCARD INTERFACE (Cont'd)**SMARTCARD ELEMENTARY TIME UNIT REGISTER (CRDETUx)****CRDETU1**

Read/Write

Reset Value: 0000 0001 (01h)

7							0
COMP	0	0	0	0	ETU10	ETU9	ETU8

Bit 7 = **COMP** *Elementary Time Unit Compensation.*

0: Compensation mode disabled.

1: Compensation mode enabled. To allow non-integer value, one clock cycle is subtracted from the ETU value on odd bits. See Figure 30.

Bit [6:3] = Reserved

Bits 2:0 = **ETU [10:8]** *ETU value in card clock cycles.*

Writing CRDETU1 register reloads the ETU counter.

CRDETU0

Read/Write

Reset Value: 0111 0100 (74h)

7							0
ETU7	ETU6	ETU5	ETU4	ETU3	ETU2	ETU1	ETU0

Bits 7:0 = **ETU [7:0]** *ETU value in card clock cycles.*

Note: The value of ETU [10:0] must in the range 12 to 2047. To write 2048, clear all the bits.

GUARDTIME REGISTER (CRDGTx)**CRDGT1**

Read/Write

Reset Value: 0000 0000 (00h)

7							0
0	0	0	0	0	0	0	GT8

CRDGT0

Read/Write

Reset Value: 0000 1100 (0Ch)

7							0
GT7	GT6	GT5	GT4	GT3	GT2	GT1	GT0

Software writes the Guardtime value in this register. The value is loaded at the end of the current Guard period.

GT: Guard Time: Minimum time between two consecutive start bits in transmission mode. Value expressed in Elementary Time Units (from 11 to 511).

The Guardtime between the last byte received from the card and the next byte transmitted by the reader must be handled by software.

SMARTCARD INTERFACE (Cont'd)

CHARACTER WAITING TIME REGISTER (CRD-WTx)

CRDWT2

Read/Write

Reset Value: 0000 0000 (00h)

CRDWT1

Read/Write

Reset Value: 0010 0101 (25h)

CRDWT0

Read/Write

Reset Value: 1000 0000 (80h)

WT: Character waiting time value expressed in ETU (0 / 16777215).

The CRDWT0, CRDWT1 and CRDWT2 registers hold the load value of the Waiting Time counter.

Note: A read operation does not return the counter value.

This counter can be used as a general purpose timer.

If the WTEN bit of the CRDCR register is reset, the counter is reloaded when a write access in the CRDWT2 register occurs. It starts when the WTEN bit is set.

If the WTEN bit in the CRDCR register is set and if UART mode is activated, the counter acts as an autoreload timer. The timer is reloaded when a start bit is sent or detected. An interrupt is generated if the timer overflows between two consecutive start bits.

Note: When loaded with a 0 value, the Waiting Time counter stays at 0 and the WTF bit = 1.

This bit is set and cleared by software to enable or disable the TXBE interrupt.

0: TXBE interrupt disabled

1: TXBE interrupt enabled

Bit 6 = Reserved.

Bit 5 = **IOVFM** *Card Overload Current Interrupt Mask.*

This bit is set and cleared by software to enable or disable the IOVF interrupt.

0: IOVF interrupt disabled

1: IOVF interrupt enabled

Bit 4= **VCRDM** *Card Voltage Error Interrupt Mask.*

This bit is set and cleared by software to enable or disable the VCRD interrupt.

0: VCRD interrupt disabled

1: VCRD interrupt enabled

Bit 3 = **WTM** *Waiting Timer Interrupt Mask.*

This bit is set and cleared by software to enable or disable the Waiting Timer overflow interrupt.

0: WT interrupt disabled

1: WT interrupt enabled

Bit 2 = **TXCM** *Transmitted Character Interrupt Mask*

This bit is set and cleared by software to enable or disable the TXC interrupt.

0: TXC interrupt disabled

1: TXC interrupt enabled

Bit 1 = **RXCM** *Received Character Interrupt Mask*

This bit is set and cleared by software to enable or disable the RXC interrupt.

0: RXC interrupt disabled

1: RXC interrupt enabled

Bit 0 = **PARM** *Parity Error Interrupt. Mask*

This bit is set and cleared by software to enable or disable the parity error interrupt for parity error.

0: PAR interrupt disabled

1: PAR error interrupt enabled

SMARTCARD INTERFACE (Cont'd)

SMARTCARD INTERRUPT PENDING REGISTER (CRDIPR)

Read Only

Reset Value: 0000 0000 (00h)

7							0
TXBE P	-	IOVF P	VCRD P	WTP	TXCP	RXC P	PAR P

This register indicates the interrupt source. It is cleared after a read operation.

Bit 7 = **TXBEP** *Transmit buffer empty interrupt pending.*

This bit is set by hardware when a TXBE event occurs and the TXBEM bit is set.
0: No TXBE interrupt pending
1: TXBE interrupt pending

Bit 6 = Reserved.

Bit 5 = **IOVF** *Card Overload Current interrupt pending.*

This bit is set by hardware when a IOVF event occurs and the IOVFM bit is set.
0: No IOVF interrupt pending
1: IOVF interrupt pending

Bit 4 = **VCRDP** *Card Voltage Error interrupt pending.*

This bit is set by hardware when the VCARDOK bit goes from 1 to 0 while the VCRDM bit is set.
0: No VCRD interrupt pending.
1: VCRD interrupt pending.

Bit 3 = **WTP** *Waiting Timer Overflow interrupt pending.*

This bit is set by hardware when a WTP event occurs and the WTPM bit is set.
0: No WT interrupt pending
1: WT interrupt pending

Bit 2 = **TXCP** *Transmitted character interrupt pending.*

This bit is set by hardware when a character is transmitted and the TXCM bit is set. It indicates

that the CRDCTXB buffer can be loaded with the next character to be transmitted.

0: No TXC interrupt pending
1: TXC interrupt pending

Bit 1 = **RXCP** *Received character interrupt pending.*

This bit is set by hardware when a character is received and the RXCM bit is set. It indicates that the CRDRXB buffer can be read.
0: No RXC interrupt pending
1: RXC interrupt pending

Bit 0 = **PARP** *Parity Error interrupt pending.*

This bit is set by hardware when a PAR event occurs and the PARM bit is set.
0: No PAR interrupt pending
1: PAR interrupt pending

13 INSTRUCTION SET

13.1 ST7 ADDRESSING MODES

The ST7 Core features 17 different addressing modes which can be classified in 7 main groups:

Addressing Mode	Example
Inherent	nop
Immediate	ld A,#\$55
Direct	ld A,\$55
Indexed	ld A,(\$55,X)
Indirect	ld A,([\$55],X)
Relative	jrne loop
Bit operation	bset byte,#5

The ST7 Instruction set is designed to minimize the number of bytes required per instruction: To do

so, most of the addressing modes may be subdivided in two sub-modes called long and short:

- Long addressing mode is more powerful because it can use the full 64 Kbyte address space, however it uses more bytes and more CPU cycles.
- Short addressing mode is less powerful because it can generally only access page zero (0000h - 00FFh range), but the instruction size is more compact, and faster. All memory to memory instructions use short addressing modes only (CLR, CPL, NEG, BSET, BRES, BTJT, BTJF, INC, DEC, RLC, RRC, SLL, SRL, SRA, SWAP)

The ST7 Assembler optimizes the use of long and short addressing modes.

Table 21. ST7 Addressing Mode Overview

Mode		Syntax	Destination	Pointer Address (Hex.)	Pointer Size (Hex.)	Length (Bytes)	
Inherent		nop				+ 0	
Immediate		ld A,#\$55				+ 1	
Short	Direct	ld A,\$10	00..FF			+ 1	
Long	Direct	ld A,\$1000	0000..FFFF			+ 2	
No Offset	Direct	Indexed	ld A,(X)	00..FF		+ 0	
Short	Direct	Indexed	ld A,(\$10,X)	00..1FE		+ 1	
Long	Direct	Indexed	ld A,(\$1000,X)	0000..FFFF		+ 2	
Short	Indirect		ld A,[\$10]	00..FF	00..FF	byte	+ 2
Long	Indirect		ld A,[\$10.w]	0000..FFFF	00..FF	word	+ 2
Short	Indirect	Indexed	ld A,([\$10],X)	00..1FE	00..FF	byte	+ 2
Long	Indirect	Indexed	ld A,([\$10.w],X)	0000..FFFF	00..FF	word	+ 2
Relative	Direct		jrne loop	PC+/-127		+ 1	
Relative	Indirect		jrne [\$10]	PC+/-127	00..FF	byte	+ 2
Bit	Direct		bset \$10,#7	00..FF		+ 1	
Bit	Indirect		bset [\$10],#7	00..FF	00..FF	byte	+ 2
Bit	Direct	Relative	btjt \$10,#7,skip	00..FF		+ 2	
Bit	Indirect	Relative	btjt [\$10],#7,skip	00..FF	00..FF	byte	+ 3

INSTRUCTION SET OVERVIEW (Cont'd)

13.1.1 Inherent

All Inherent instructions consist of a single byte. The opcode fully specifies all the required information for the CPU to process the operation.

Inherent Instruction	Function
NOP	No operation
TRAP	S/W Interrupt
WFI	Wait For Interrupt (Low Power Mode)
HALT	Halt Oscillator (Lowest Power Mode)
RET	Sub-routine Return
IRET	Interrupt Sub-routine Return
SIM	Set Interrupt Mask (level 3)
RIM	Reset Interrupt Mask (level 0)
SCF	Set Carry Flag
RCF	Reset Carry Flag
RSP	Reset Stack Pointer
LD	Load
CLR	Clear
PUSH/POP	Push/Pop to/from the stack
INC/DEC	Increment/Decrement
TNZ	Test Negative or Zero
CPL, NEG	1 or 2 Complement
MUL	Byte Multiplication
SLL, SRL, SRA, RLC, RRC	Shift and Rotate Operations
SWAP	Swap Nibbles

13.1.2 Immediate

Immediate instructions have two bytes, the first byte contains the opcode, the second byte contains the operand value.

Immediate Instruction	Function
LD	Load
CP	Compare
BCP	Bit Compare
AND, OR, XOR	Logical Operations
ADC, ADD, SUB, SBC	Arithmetic Operations

13.1.3 Direct

In Direct instructions, the operands are referenced by their memory address.

The direct addressing mode consists of two sub-modes:

Direct (short)

The address is a byte, thus requires only one byte after the opcode, but only allows 00 - FF addressing space.

Direct (long)

The address is a word, thus allowing 64 Kbyte addressing space, but requires 2 bytes after the opcode.

13.1.4 Indexed (No Offset, Short, Long)

In this mode, the operand is referenced by its memory address, which is defined by the unsigned addition of an index register (X or Y) with an offset.

The indirect addressing mode consists of three sub-modes:

Indexed (No Offset)

There is no offset, (no extra byte after the opcode), and allows 00 - FF addressing space.

Indexed (Short)

The offset is a byte, thus requires only one byte after the opcode and allows 00 - 1FE addressing space.

Indexed (long)

The offset is a word, thus allowing 64 Kbyte addressing space and requires 2 bytes after the opcode.

13.1.5 Indirect (Short, Long)

The required data byte to do the operation is found by its memory address, located in memory (pointer).

The pointer address follows the opcode. The indirect addressing mode consists of two sub-modes:

Indirect (short)

The pointer address is a byte, the pointer size is a byte, thus allowing 00 - FF addressing space, and requires 1 byte after the opcode.

Indirect (long)

The pointer address is a byte, the pointer size is a word, thus allowing 64 Kbyte addressing space, and requires 1 byte after the opcode.

INSTRUCTION SET OVERVIEW (Cont'd)**13.1.6 Indirect Indexed (Short, Long)**

This is a combination of indirect and short indexed addressing modes. The operand is referenced by its memory address, which is defined by the unsigned addition of an index register value (X or Y) with a pointer value located in memory. The pointer address follows the opcode.

The indirect indexed addressing mode consists of two sub-modes:

Indirect Indexed (Short)

The pointer address is a byte, the pointer size is a byte, thus allowing 00 - 1FE addressing space, and requires 1 byte after the opcode.

Indirect Indexed (Long)

The pointer address is a byte, the pointer size is a word, thus allowing 64 Kbyte addressing space, and requires 1 byte after the opcode.

Table 22. Instructions Supporting Direct, Indexed, Indirect and Indirect Indexed Addressing Modes

Long and Short Instructions	Function
LD	Load
CP	Compare
AND, OR, XOR	Logical Operations
ADC, ADD, SUB, SBC	Arithmetic Additions/Subtractions operations
BCP	Bit Compare

Short Instructions Only	Function
CLR	Clear
INC, DEC	Increment/Decrement
TNZ	Test Negative or Zero
CPL, NEG	1 or 2 Complement
BSET, BRES	Bit Operations
BTJT, BTJF	Bit Test and Jump Operations
SLL, SRL, SRA, RLC, RRC	Shift and Rotate Operations
SWAP	Swap Nibbles
CALL, JP	Call or Jump subroutine

13.1.7 Relative mode (Direct, Indirect)

This addressing mode is used to modify the PC register value, by adding an 8-bit signed offset to it.

Available Relative Direct/Indirect Instructions	Function
JRxx	Conditional Jump
CALLR	Call Relative

The relative addressing mode consists of two sub-modes:

Relative (Direct)

The offset is following the opcode.

Relative (Indirect)

The offset is defined in memory, which address follows the opcode.

INSTRUCTION SET OVERVIEW (Cont'd)

13.2 INSTRUCTION GROUPS

The ST7 family devices use an Instruction Set consisting of 63 instructions. The instructions may

be subdivided into 13 main groups as illustrated in the following table:

Load and Transfer	LD	CLR						
Stack operation	PUSH	POP	RSP					
Increment/Decrement	INC	DEC						
Compare and Tests	CP	TNZ	BCP					
Logical operations	AND	OR	XOR	CPL	NEG			
Bit Operation	BSET	BRES						
Conditional Bit Test and Branch	BTJT	BTJF						
Arithmetic operations	ADC	ADD	SUB	SBC	MUL			
Shift and Rotates	SLL	SRL	SRA	RLC	RRC	SWAP	SLA	
Unconditional Jump or Call	JRA	JRT	JRF	JP	CALL	CALLR	NOP	RET
Conditional Branch	JRxx							
Interrupt management	TRAP	WFI	HALT	IRET				
Condition Code Flag modification	SIM	RIM	SCF	RCF				

Using a pre-byte

The instructions are described with one to four opcodes.

In order to extend the number of available opcodes for an 8-bit CPU (256 opcodes), three different prebyte opcodes are defined. These prebytes modify the meaning of the instruction they precede.

The whole instruction becomes:

PC-2 End of previous instruction
 PC-1 Prebyte
 PC opcode
 PC+1 Additional word (0 to 2) according to the number of bytes required to compute the effective address

These prebytes enable instruction in Y as well as indirect addressing modes to be implemented. They precede the opcode of the instruction in X or the instruction using direct addressing mode. The prebytes are:

PDY 90 Replace an X based instruction using immediate, direct, indexed, or inherent addressing mode by a Y one.

PIX 92 Replace an instruction using direct, direct bit, or direct relative addressing mode to an instruction using the corresponding indirect addressing mode.

It also changes an instruction using X indexed addressing mode to an instruction using indirect X indexed addressing mode.

PIY 91 Replace an instruction using X indirect indexed addressing mode by a Y one.

INSTRUCTION SET OVERVIEW (Cont'd)

Mnemo	Description	Function/Example	Dst	Src	I1	H	I0	N	Z	C
JRULE	Jump if (C + Z = 1)	Unsigned <=								
LD	Load	dst <= src	reg, M	M, reg				N	Z	
MUL	Multiply	X,A = X * A	A, X, Y	X, Y, A		0				0
NEG	Negate (2's compl)	neg \$10	reg, M					N	Z	C
NOP	No Operation									
OR	OR operation	A = A + M	A	M				N	Z	
POP	Pop from the Stack	pop reg	reg	M						
		pop CC	CC	M	I1	H	I0	N	Z	C
PUSH	Push onto the Stack	push Y	M	reg, CC						
RCF	Reset carry flag	C = 0								0
RET	Subroutine Return									
RIM	Enable Interrupts	I1:0 = 10 (level 0)			1		0			
RLC	Rotate left true C	C <= A <= C	reg, M					N	Z	C
RRC	Rotate right true C	C => A => C	reg, M					N	Z	C
RSP	Reset Stack Pointer	S = Max allowed								
SBC	Substract with Carry	A = A - M - C	A	M				N	Z	C
SCF	Set carry flag	C = 1								1
SIM	Disable Interrupts	I1:0 = 11 (level 3)			1		1			
SLA	Shift left Arithmetic	C <= A <= 0	reg, M					N	Z	C
SLL	Shift left Logic	C <= A <= 0	reg, M					N	Z	C
SRL	Shift right Logic	0 => A => C	reg, M					0	Z	C
SRA	Shift right Arithmetic	A7 => A => C	reg, M					N	Z	C
SUB	Substraction	A = A - M	A	M				N	Z	C
SWAP	SWAP nibbles	A7-A4 <=> A3-A0	reg, M					N	Z	
TNZ	Test for Neg & Zero	tnz !b1						N	Z	
TRAP	S/W trap	S/W interrupt			1		1			
WFI	Wait for Interrupt				1		0			
XOR	Exclusive OR	A = A XOR M	A	M				N	Z	

14 ELECTRICAL CHARACTERISTICS

14.1 ABSOLUTE MAXIMUM RATINGS

This product contains devices for protecting the inputs against damage due to high static voltages, however it is advisable to take normal precautions to avoid applying any voltage higher than the specified maximum rated voltages.

For proper operation it is recommended that V_I and V_O be higher than V_{SS} and lower than V_{DD} . Reliability is enhanced if unused inputs are connected to an appropriate logic voltage level (V_{DD} or V_{SS}).

Power Considerations. The average chip-junction temperature, T_J , in Celsius can be obtained from:

Where:

$$T_J = T_A + P_D \times R_{thJA}$$

$$T_A = \text{Ambient Temperature.}$$

$$R_{thJA} = \text{Package thermal resistance (junction-to ambient).}$$

$$P_D = P_{INT} + P_{PORT}$$

$$P_{INT} = I_{DD} \times V_{DD} \text{ (chip internal power).}$$

$$P_{PORT} = \text{Port power dissipation determined by the user}$$

Stresses above those listed as “absolute maximum ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these conditions is not implied. Exposure to maximum rating for extended periods may affect device reliability.

Symbol	Ratings	Value	Unit
$V_{DD} - V_{SS}$	Supply voltage	6.0	V
V_{IN}	Input voltage	$V_{SS} - 0.3$ to $V_{DD} + 0.3$	V
V_{OUT}	Output voltage	$V_{SS} - 0.3$ to $V_{DD} + 0.3$	V
ESD	ESD susceptibility	2000	V
ESDCard	ESD susceptibility for card pads	4000	V
I_{VDD_i}	Total current into V_{DD_i} (source)	250	mA
I_{VSS_i}	Total current out of V_{SS_i} (sink)	250	

General Warning: Direct connection to V_{DD} or V_{SS} of the I/O pins could damage the device in case of program counter corruption (due to unwanted change of the I/O configuration). To guarantee safe conditions, this connection has to be done through a typical 10K Ω pull-up or pull-down resistor.

Thermal Characteristics

Symbol	Ratings	Value	Unit
R_{thJA}	Package thermal resistance	TQFP64	60
		SO24	80
T_{Jmax}	Max. junction temperature	150	$^{\circ}\text{C}$
T_{STG}	Storage temperature range	-65 to +150	$^{\circ}\text{C}$
PD	Power dissipation (maximum value)	500	mW

14.2 RECOMMENDED OPERATING CONDITIONS

GENERAL						
Symbol	Parameter	Conditions	Min	Typ	Max	Unit
V_{DD}	Supply voltage		4.0		5.5	V
f_{OSC}	External clock source			4		MHz
T_A	Ambient temperature range		0		70	°C

(Operating conditions $T_A = 0$ to $+70^\circ\text{C}$ unless otherwise specified)

CURRENT INJECTION ON I/O PORT AND CONTROL PINS						
Symbol	Parameter	Conditions	Min	Typ	Max	Unit
I_{INJ+}	Total positive injected current ⁽¹⁾	$V_{EXTERNAL} > V_{DD}$ (Standard I/Os) $V_{EXTERNAL} > V_{SC_PWR}$ (Smartcard I/Os)			20	mA
I_{INJ-}	Total negative injected current ^(2,3)	$V_{EXTERNAL} < V_{SS}$ Digital pins Analog pins			20	mA

Note 1: Positive injection

The I_{INJ+} is done through protection diodes insulated from the substrate of the die.

Note 2: For SmartCard I/Os, V_{CARD} has to be considered.

Note 3: Negative injection

– The I_{INJ-} is done through protection diodes NOT INSULATED from the substrate of the die. The drawback is a small leakage (few μA) induced inside the die when a negative injection is performed. This leakage is tolerated by the digital structure, but it acts on the analog line according to the impedance versus a leakage current of few μA (if the MCU has an AD converter). The effect depends on the pin which is submitted to the injection. Of course, external digital signals applied to the component must have a maximum impedance close to $50\text{K}\Omega$.

Location of the negative current injection:

– Pure digital pins can tolerate 1.6mA. In addition, the best choice is to inject the current as far as possible from the analog input pins.

General Note: When several inputs are submitted to a current injection, the maximum I_{INJ} is the sum of the positive (resp. negative) currents (instantaneous values).

RECOMMENDED OPERATING CONDITIONS (Cont'd)

($T_A=0$ to $+70^{\circ}\text{C}$, $V_{DD}-V_{SS}=5.5\text{V}$ unless otherwise specified)

Symbol	Parameter	Conditions	Min	Typ.	Max	Unit
I_{DD}	Supply current in RUN mode ¹⁾	$f_{OSC} = 4\text{MHz}$		10	15	mA
	Supply current in WAIT mode ²⁾			3		
	Supply current in suspend mode	External $I_{LOAD} = 0\text{mA}$ (USB transceiver enabled)			500	μA
	Supply current in HALT mode	External $I_{LOAD} = 0\text{mA}$ (USB transceiver disabled)		50	100	

Notes:

- CPU running with memory access, all I/O pins in input mode with a static value at V_{DD} or V_{SS} ; clock input (OSC1) driven by external square wave.
 - All I/O pins in input mode with a static value at V_{DD} or V_{SS} ; clock input (OSC1) driven by external square wave.
- $T = 0 \dots +70^{\circ}\text{C}$, voltages are referred to V_{SS} unless otherwise specified:

I/O PORT PINS						
Symbol	Parameter	Conditions	Min	Typ	Max	Unit
V_{IL}	Input low level voltage				$0.3 \times V_{DD}$	V
V_{IH}	Input high level voltage		$0.7 \times V_{DD}$			
V_{HYS}	Schmidt trigger voltage hysteresis ¹⁾			400		mV
V_{OL}	Output low level voltage for Standard I/O port pins	$I = -5\text{mA}$			1.3	V
		$I = -2\text{mA}$			0.4	
V_{OH}	Output high level voltage	$I = 3\text{mA}$	$V_{DD} - 0.8$			
I_L	Input leakage current	$V_{SS} < V_{PIN} < V_{DD}$			1	μA
R_{PU}	Pull-up equivalent resistor		50	90	170	$\text{K}\Omega$
t_{OHL}	Output high to low level fall time for high sink I/O port pins (Port D) ²⁾	$C_I = 50\text{pF}$	6	8	13	ns
t_{OHL}	Output high to low level fall time for standard I/O port pins (Port A, B or C) ²⁾		18		23	
t_{OLH}	Output L-H rise time (Port D) ²⁾		7	9	14	
t_{OLH}	Output L-H rise time for standard I/O port pins (Port A, B or C) ²⁾		19		28	
t_{TEXT}	External interrupt pulse time		1			t_{CPU}

Note 1 : Hysteresis voltage between Schmitt trigger switching levels. Based on characterisation results, not tested.

Note 2 : Guaranteed by Characterization

LED PINS						
Symbol	Parameter	Conditions	Min	Typ	Max	Unit
$I_{L\text{sink}}$	Low current	$V_{pad} > V_{DD} - 2.4$	2		4	mA
$I_{L\text{sink}}$	High current	$V_{pad} > V_{DD} - 2.4$	5.6		8.4	

14.3 SUPPLY AND RESET CHARACTERISTICS

($T = 0$ to $+70^{\circ}\text{C}$, $V_{\text{DD}} - V_{\text{SS}} = 5.5\text{V}$ unless otherwise specified.)

LOW VOLTAGE DETECTOR AND SUPERVISOR (LVDS)						
Symbol	Parameter	Conditions	Min	Typ	Max	Unit
$V_{\text{IT+}}$	Reset release threshold (V_{DD} rising)			3.7	3.9	V
$V_{\text{IT-}}$	Reset generation threshold (V_{DD} falling)		3.3	3.5		V
V_{hys}	Hysteresis $V_{\text{IT+}} - V_{\text{IT-}}$			200		mV
V_{tPOR}	V_{DD} rise time rate		20			ms/V

14.4 CLOCK AND TIMING CHARACTERISTICS

14.4.1 General Timings

(Operating conditions $T_{\text{A}} = 0$ to $+70^{\circ}\text{C}$ unless otherwise specified)

Symbol	Parameter	Conditions	Min	Typ ¹⁾	Max	Unit
$t_{\text{c(INST)}}$	Instruction cycle time		2	3	12	t_{CPU}
		$f_{\text{CPU}}=4\text{MHz}$	500	750	3000	ns
$t_{\text{v(IT)}}$	Interrupt reaction time ²⁾ $t_{\text{v(IT)}} = \Delta t_{\text{c(INST)}} + 10$		10		22	t_{CPU}
		$f_{\text{CPU}}=4\text{MHz}$	2.5		5.5	μs

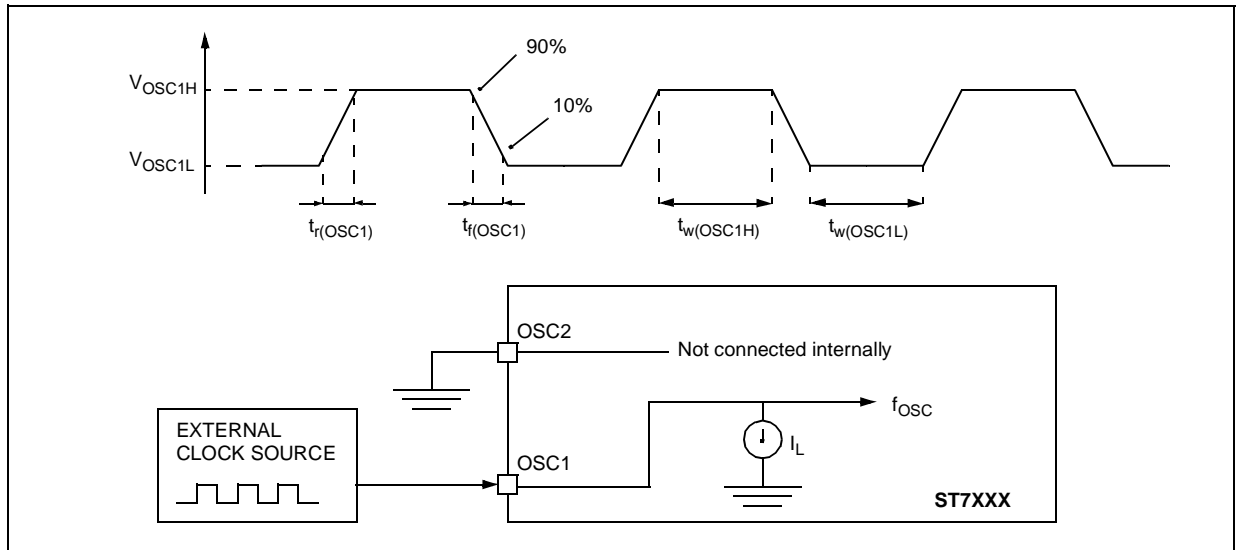

* Δt_{INST} is the number of t_{CPU} to finish the current instruction execution.

14.4.2 External Clock Source

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
V_{OSC1H}	OSC1 input pin high level voltage	see Figure 38	$0.7 \times V_{\text{DD}}$		V_{DD}	V
V_{OSC1L}	OSC1 input pin low level voltage		V_{SS}		$0.3 \times V_{\text{DD}}$	
$t_{\text{w(OSC1H)}}$ $t_{\text{w(OSC1L)}}$	OSC1 high or low time ³⁾		15			ns
$t_{\text{r(OSC1)}}$ $t_{\text{f(OSC1)}}$	OSC1 rise or fall time ³⁾				15	
I_{L}	OSCx Input leakage current		$V_{\text{SS}} \leq V_{\text{IN}} \leq V_{\text{DD}}$			± 1

CLOCK AND TIMING CHARACTERISTICS (Cont'd)

Figure 38. Typical Application with an External Clock Source

Notes:

1. Data based on typical application software.
2. Time measured between interrupt event and interrupt vector fetch. $\Delta t_{c(INST)}$ is the number of t_{CPU} cycles needed to finish the current instruction execution.
3. Data based on design simulation and/or technology characteristics, not tested in production.

CLOCK AND TIMING CHARACTERISTICS (Cont'd)

14.4.3 Crystal Resonator Oscillators

The ST7 internal clock is supplied with one Crystal resonator oscillator. All the information given in this paragraph are based on characterization results with specified typical external components. In the application, the resonator and the load capaci-

tors have to be placed as close as possible to the oscillator pins in order to minimize output distortion and start-up stabilization time. Refer to the crystal resonator manufacturer for more details (frequency, package, accuracy...).

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
f_{OSC}	Oscillator Frequency ³⁾	MP: Medium power oscillator		4		MHz
R_F	Feedback resistor		20		40	k Ω
C_{L1} C_{L2}	Recommended load capacitances versus equivalent serial resistance of the crystal resonator (R_S)	See Table 4 on page 20 (MP oscillator)	22		56	pF
i_2	OSC2 driving current	$V_{DD}=5V$ $V_{IN}=V_{SS}$ (MP oscillator)	110		190	μA

Oscil.	Typical Crystal Resonator					C_{L1} [pF]	C_{L2} [pF]	$t_{SU(osc)}$ [ms] ²⁾
	Reference		Freq.	Characteristic ¹⁾				
Crysta MP	JAUCH	SS3-400-30-30/30	4MHz	$\Delta f_{OSC}=[\pm 30ppm_{25^\circ C}, \pm 30ppm_{\Delta Ta}]$, Typ. $R_S=60\Omega$		33	34	7~10

Figure 39. Typical Application with a Crystal Resonator

Notes:

1. Resonator characteristics given by the crystal resonator manufacturer.
2. $t_{SU(OSC)}$ is the typical oscillator start-up time measured between $V_{DD}=2.8V$ and the fetch of the first instruction (with a quick V_{DD} ramp-up from 0 to 5V (<50 μs).
3. The oscillator selection can be optimized in terms of supply current using an high quality resonator with small R_S value. Refer to crystal resonator manufacturer for more details.

14.5 MEMORY CHARACTERISTICS

Subject to general operating conditions for V_{DD} , f_{OSC} , and T_A unless otherwise specified.

14.5.1 RAM and Hardware Registers

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
V_{RM}	Data retention mode ¹⁾	HALT mode (or RESET)	2			V

14.5.2 FLASH Memory

Operating Conditions: $f_{CPU} = 8$ MHz.

DUAL VOLTAGE FLASH MEMORY						
Symbol	Parameter	Conditions	Min	Typ	Max	Unit
f_{CPU}	Operating Frequency	Read mode			8	MHz
		Write / Erase mode, $T_A=25^\circ\text{C}$			8	
V_{PP}	Programming Voltage	$4.0\text{V} \leq V_{DD} \leq 5.5\text{V}$	11.4		12.6	V
I_{PP}	V_{PP} Current	Write / Erase			30	mA
t_{PROG}	Byte Programming Time	$T_A=25^\circ\text{C}$		100	500	μs
t_{ERASE}	Sector Erasing Time		2	10	sec	
	Device Erasing Time		5	10		
t_{VPP}	Internal V_{PP} Stabilization Time			10		μs
t_{RET}	Data Retention	$T_A \leq 55^\circ\text{C}$	20			years
N_{RW}	Write Erase Cycles	$T_A=25^\circ\text{C}$	100			cycles

Warning: Do not connect 12V to V_{PP} before V_{DD} is powered on, as this may damage the device.

14.6 SMARTCARD SUPPLY SUPERVISOR ELECTRICAL CHARACTERISTICS

($T_A = 0... +70^\circ\text{C}$, $4.0 < V_{DD} - V_{SS} < 5.5\text{V}$ unless otherwise specified)

SMARTCARD SUPPLY SUPERVISOR						
Symbol	Parameter	Conditions	Min	Typ	Max	Unit
5V regulator output (for IEC7816-3 Class A Cards)						
V_{CARD}	SmartCard Power Supply Voltage		4.6	5.00	5.4	V
I_{SC}	SmartCard Supply Current				55	mA
I_{OVDET}	Current Overload Detection				120 ¹⁾	mA
t_{IDET}	Detection time on Current Overload		170 ¹⁾		1400 ¹⁾	μs
t_{OFF}	V_{CARD} Turn off Time (see Figure 35 on page 61)	$C_{LOADmax} \leq 4.7\mu\text{F}$			750	μs
t_{ON}	V_{CARD} Turn on Time (see Figure 35 on page 61)	$C_{LOADmax} \leq 4.7\mu\text{F}$		150	500	μs
I_{VDD}	V_{DD} supply current	See note			100	mA
3V regulator output (for IEC7816-3 Class B Cards)						
V_{CARD}	SmartCard Power Supply Voltage		2.7		3.3	V
I_{SC}	SmartCard Supply Current				50	mA
I_{OVDET}	Current Overload Detection				100 ¹⁾	mA
t_{IDET}	Detection time on Current Overload		170 ¹⁾		1400 ¹⁾	us
t_{OFF}	V_{CARD} Turn off Time (see Figure 35 on page 61)	$C_{LOADmax} \leq 4.7\mu\text{F}$			750	us

SMARTCARD SUPPLY SUPERVISOR						
Symbol	Parameter	Conditions	Min	Typ	Max	Unit
t_{ON}	V_{CARD} Turn on Time (see Figure 35 on page 61)	$C_{LOADmax} \leq 4.7\mu F$		150	500	μs
1.8V regulator output (for IEC7816-3 Class C Cards)						
V_{CARD}	SmartCard Power Supply Voltage		1.65		1.95	V
I_{SC}	SmartCard Supply Current				20	mA
I_{OVDET}	Current Overload Detection				100 ¹⁾	mA
t_{IDET}	Detection time on Current Overload		170 ¹⁾		1400 ¹⁾	us
t_{OFF}	V_{CARD} Turn off Time (see Figure 35 on page 61)	$C_{LOADmax} \leq 4.7\mu F$			750	us
t_{ON}	V_{CARD} Turn on Time (see Figure 35 on page 61)	$C_{LOADmax} \leq 4.7\mu F$		150	500	μs
Smartcard CLKPin						
V_{OL}	Output Low Level Voltage	$I = -50\mu A$	-	-	0.4 ²⁾	V
V_{OH}	Output High Level Voltage	$I = 50\mu A$	$V_{CARD} - 0.5$ ²⁾	-	-	V
T_{OHL}	Output H-L Fall Time	$C_i = 30pF$	-		20	ns
T_{OLH}	Output L-H Rise Time	$C_i = 30pF$	-		20	ns
F_{VAR}	Frequency variation		-		1	%
F_{DUTY}	Duty cycle		45		55	%
I_{SGND}	Short-circuit to Ground			15		mA
Smartcard I/O Pin						
V_{IL}	Input Low Level Voltage		-	-	0.5 ²⁾	V
V_{IH}	Input High Level Voltage		$0.6V_{CARD}$ ²⁾	-	-	V
V_{OL}	Output Low Level Voltage	$I = -0.5mA$	-	-	0.4 ²⁾	V
V_{OH}	Output High Level Voltage	$I = 20\mu A$	$0.8V_{CARD}$ ²⁾	-	V_{CARD} ²⁾	V
I_L	Input Leakage Current	$V_{SS} < V_{IN} < V_{SC_PWR}$	-10	-	10	μA
I_{RPU}	Pull-up Equivalent Resistance	$V_{IN} = V_{SS}$		24	30	K Ω
T_{OHL}	Output H-L Fall Time	$C_i = 30pF$	-		0.8	us
T_{OLH}	Output L-H Rise Time	$C_i = 30pF$	-		0.8	us
I_{SGND}	Short-circuit to Ground			15		mA
Smartcard RST C4 and C8 Pin						
V_{OL}	Output Low Level Voltage	$I = -0.5mA$	-	-	0.4 ²⁾	V
V_{OH}	Output High Level Voltage	$I = 20\mu A$	$V_{CARD} - 0.5$ ²⁾	-	V_{CARD} ²⁾	V
T_{OHL}	Output H-L Fall Time	$C_i = 30pF$	-		0.8	us
T_{OLH}	Output L-H Rise Time	$C_i = 30pF$	-		0.8	us
I_{SGND}	Short-circuit to Ground			15		mA

Note 1 : Guaranteed by design.

Note 2 : Data based on characterization results, not tested in production.

Notes: $V_{DD} = 4.75 V$, Card consumption = 55mA, CRDCLK frequency = 4MHz, LED with a 3mA current, USB in reception mode and CPU in WFI mode.

14.7 EMC CHARACTERISTICS

Susceptibility tests are performed on a sample basis during product characterization.

14.7.1 Functional EMS

(Electro Magnetic Susceptibility)

Based on a simple running application on the product (toggling 2 LEDs through I/O ports), the product is stressed by two electro magnetic events until a failure occurs (indicated by the LEDs).

- ESD: Electro-Static Discharge (positive and negative) is applied on all pins of the device until a functional disturbance occurs. This test conforms with the IEC 1000-4-2 standard.
- FTB: A Burst of Fast Transient voltage (positive and negative) is applied to V_{DD} and V_{SS} through a 100pF capacitor, until a functional disturbance occurs. This test conforms with the IEC 1000-4-4 standard.

A device reset allows normal operations to be resumed.

Symbol	Parameter	Conditions	Neg ¹⁾	Pos ¹⁾	Unit
V_{FESD}	Voltage limits to be applied on any I/O pin to induce a functional disturbance	$V_{DD}=5V$, $T_A=+25^{\circ}C$, $f_{OSC}=8MHz$ conforms to IEC 1000-4-2	1	0.7	kV
V_{FFTB}	Fast transient voltage burst limits to be applied through 100pF on V_{DD} and V_{DD} pins to induce a functional disturbance	$V_{DD}=5V$, $T_A=+25^{\circ}C$, $f_{OSC}=8MHz$ conforms to IEC 1000-4-4	2	2	

Notes:

1. Data based on characterization results, not tested in production.

EMC CHARACTERISTICS (Cont'd)

14.7.2 Absolute Electrical Sensitivity

Based on three different tests (ESD, LU and DLU) using specific measurement methods, the product is stressed in order to determine its performance in terms of electrical sensitivity. For more details, refer to the AN1181 ST7 application note.

14.7.2.1 Electro-Static Discharge (ESD)

Electro-Static Discharges (1 positive then 1 negative pulse separated by 1 second) are applied to the pins of each sample according to each pin combination. The sample size depends of the number of supply pins of the device (3 parts*(n+1) supply pin). The Human Body Model is simulated. This test conforms to the JESD22-A114A standard. See Figure 40 and the following test sequences.

Human Body Model Test Sequence

- C_L is loaded through S1 by the HV pulse generator.
- S1 switches position from generator to R.
- A discharge from C_L through R (body resistance) to the ST7 occurs.
- S2 must be closed 10 to 100ms after the pulse delivery period to ensure the ST7 is not left in charge state. S2 must be opened at least 10ms prior to the delivery of the next pulse.

14.7.2.2 Designing hardened software to avoid noise problems

EMC characterization and optimization are performed at component level with a typical application environment and simplified MCU software. It should be noted that good EMC performance is highly dependent on the user application and the software in particular.

Therefore it is recommended that the user applies EMC software optimization and prequalification tests in relation with the EMC level requested for his application.

Software recommendations:

The software flowchart must include the management of runaway conditions such as:

- Corrupted program counter
- Unexpected reset
- Critical Data corruption (control registers...)

Prequalification trials:

Most of the common failures (unexpected reset and program counter corruption) can be reproduced by manually forcing a low state on the RESET pin or the Oscillator pins for 1 second.

To complete these trials, ESD stress can be applied directly on the device, over the range of specification values. When unexpected behaviour is detected, the software can be hardened to prevent unrecoverable errors occurring (see application note AN1015).

Absolute Maximum Ratings

Symbol	Ratings	Conditions	Maximum value ¹⁾	Unit
$V_{ESD(HBM)}$	Electro-static discharge voltage (Human Body Model)	$T_A=+25^{\circ}C$	1500	V

Figure 40. Typical Equivalent ESD Circuits

Notes:

1. Data based on characterization results, not tested in production.

EMC CHARACTERISTICS (Cont'd)

14.7.2.3 Static and Dynamic Latch-Up

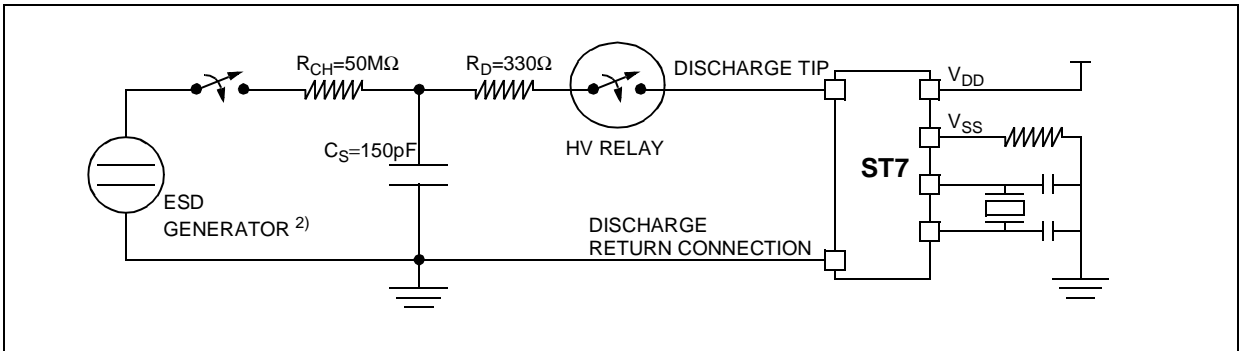

■ LU: 3 complementary static tests are required on 10 parts to assess the latch-up performance. A supply overvoltage (applied to each power supply pin), a current injection (applied to each input, output and configurable I/O pin) and a power supply switch sequence are performed on each sample. This test conforms to the EIA/JESD 78 IC latch-up standard. For more details, refer to the AN1181 ST7 application note.

■ DLU: Electro-Static Discharges (one positive then one negative test) are applied to each pin of 3 samples when the micro is running to assess the latch-up performance in dynamic mode. Power supplies are set to the typical values, the oscillator is connected as near as possible to the pins of the micro and the component is put in reset mode. This test conforms to the IEC1000-4-2 and SAEJ1752/3 standards and is described in Figure 41. For more details, refer to the AN1181 ST7 application note.

Electrical Sensitivities

Symbol	Parameter	Conditions	Class ¹⁾
LU	Static latch-up class	$T_A=+25^{\circ}\text{C}$	A
DLU	Dynamic latch-up class	$V_{DD}=5.5\text{V}$, $f_{OSC}=4\text{MHz}$, $T_A=+25^{\circ}\text{C}$	A

Figure 41. Simplified Diagram of the ESD Generator for DLU

Notes:

1. Class description: A Class is an STMicroelectronics internal specification. All its limits are higher than the JEDEC specifications, that means when a device belongs to Class A it exceeds the JEDEC standard. B Class strictly covers all the JEDEC criteria (international standard).
2. Schaffner NSG435 with a pointed test finger.

EMC CHARACTERISTICS (Cont'd)

14.7.3 ESD Pin Protection Strategy

To protect an integrated circuit against Electro-Static Discharge the stress must be controlled to prevent degradation or destruction of the circuit elements. The stress generally affects the circuit elements which are connected to the pads but can also affect the internal devices when the supply pads receive the stress. The elements to be protected must not receive excessive current, voltage or heating within their structure.

An ESD network combines the different input and output ESD protections. This network works, by allowing safe discharge paths for the pins subjected to ESD stress. Two critical ESD stress cases are presented in Figure 42 and Figure 43 for standard pins.

Standard Pin Protection

To protect the output structure the following elements are added:

- A diode to V_{DD} (3a) and a diode from V_{SS} (3b)
- A protection device between V_{DD} and V_{SS} (4)

To protect the input structure the following elements are added:

- A resistor in series with the pad (1)
- A diode to V_{DD} (2a) and a diode from V_{SS} (2b)
- A protection device between V_{DD} and V_{SS} (4)

Figure 42. Positive Stress on a Standard Pad vs. V_{SS}

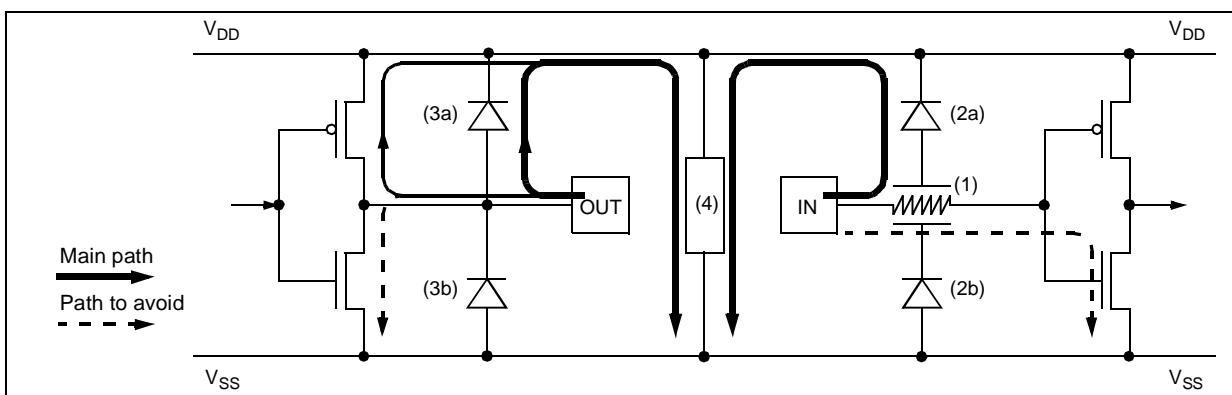

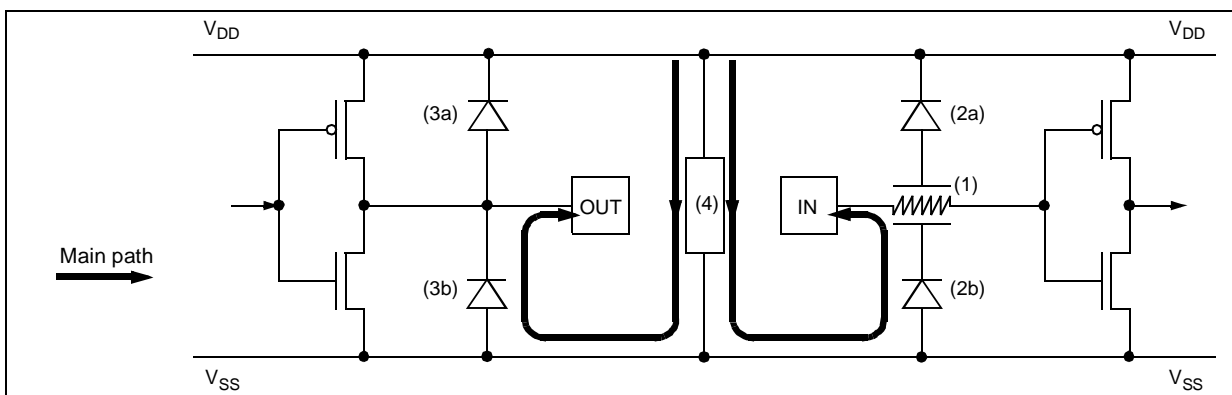

Figure 43. Negative Stress on a Standard Pad vs. V_{DD}

EMC CHARACTERISTICS (Cont'd)**Multisupply Configuration**

When several types of ground (V_{SS} , V_{SSA} , ...) and power supply (V_{DD} , V_{DDA} , ...) are available for any reason (better noise immunity...), the structure

shown in Figure 44 is implemented to protect the device against ESD.

Figure 44. Multisupply Configuration

14.8 COMMUNICATION INTERFACE CHARACTERISTICS

14.8.1 USB - Universal Bus Interface

USB DC Electrical Characteristics					
Parameter	Symbol	Conditions	Min.	Max.	Unit
Input Levels:					
Differential Input Sensitivity	VDI	I(D+, D-)	0.2		V
Differential Common Mode Range	VCM	Includes VDI range	0.8	2.5	V
Single Ended Receiver Threshold	VSE		1.3	2.0	V
Output Levels					
Static Output Low	VOL	RL of 1.5K ohms to 3.6v		0.3	V
Static Output High	VOH	RL of 15K ohm to V _{SS}	2.8	3.6	V
USBVCC: voltage level	USBV	V _{DD} =5v	3.00	3.60	V

Note 1: RL is the load connected on the USB drivers.

Note 2: All the voltages are measured from the local ground potential.

16 DEVICE CONFIGURATION AND ORDERING INFORMATION

Each device is available for production in ROM versions and in user programmable versions (High Density FLASH).

FLASH devices are shipped to customers with a default content (FFh).

This implies that FLASH devices have to be configured by the customer using the Option Byte while the ROM devices are factory-configured.

16.0.1 Option Bytes

The 8 option bits from the flash are programmed through the static option byte SOB1. The description of each of these 8 bits is given below.

Static option Byte (SOB1)

OPT 7	6	5	4	3	2	1	OPT 0
--	--	WDG- SW	NEST	SOCLK	RETRY	-	FMP_R

OPT7:6 = Reserved

OPT5= **WDGSW** *Hardware or software watchdog*

This option bit selects the watchdog type.

0: Hardware (watchdog always activated)

1: Software (watchdog to be activated by software)

OPT4 = **NEST** *Interrupt Controller*

This bit enables the nested Interrupt Controller.

0: Nested interrupt controller disabled

1: Nested interrupt controller enabled

OPT3 = **ISOCLK** *Clock source selection*

0: Card clock is generated by the divider (48MHz/12 = 4MHz).

1: Card clock is generated by the oscillator.

OPT2 = **RETRY** *Number of Retries for UART ISO*

0: In case of an erroneous transfer, character is transmitted 4 times.

1: In case of an erroneous transfer, character is transmitted 5 times.

OPT1 = Reserved, must be kept at 1.

OPT0 = **FMP_R** *Flash memory read-out protection*

This option indicates if the user flash memory is protected against read-out piracy. This protection is based on read and a write protection of the memory in test modes and ICP mode. Erasing the option bytes when the FMP_R option is selected induce the whole user memory erasing first.

0 : read-out protection enabled

1 : read-out protection disabled

16.1 DEVICE ORDERING INFORMATION AND TRANSFER OF CUSTOMER CODE

Customer code is made up of the ROM contents and the list of the selected options (if any). The ROM contents are to be sent on diskette, or by electronic means, with the hexadecimal file in .S19 format generated by the development tool. All unused bytes must be set to FFh.

The selected options are communicated to STMicroelectronics using the correctly completed OPTION LIST appended. See page 94.

The STMicroelectronics Sales Organization will be pleased to provide detailed information on contractual points.

17 SUMMARY OF CHANGES

Description of the changes between the current release of the specification and the previous one.

Revision	Main changes	Date
1.2	Removed LVD option bit (LVD cannot be disabled) Updated Figure 7 on page 15	Dec-01
1.3	Changed status of the document Changed Table 1, "Device Summary," on page 1 Changed Figure 4 on page 10 Changed Section 4.2 on page 14 Added note in Section 4.5 on page 15 Changed description of the following registers in Section 12.3.4 on page 46: EP0R, Endpoint Transmission Register and Endpoint 2 Reception Register. Moved "Power Supply Management" chapter to Section 12.4.3.1 on page 56 Updated Section 14 on page 76 Added Section 14.7 on page 84 Changed Figure 46 on page 90 Removed references to true open drain pins Changed Section 16.1 on page 93 Added warning in Section 14.5.2 on page 82 Added Erratasheet on page 99	March-03

ST7SCR LIMITATIONS AND CORRECTIONS

18 SILICON IDENTIFICATION

This document refers only to ST7FSCR devices shown in Table 25. They are identifiable both by the last letter of the **Trace code** marked on the device package and by the last 3 digits of the **Internal Sales Type** printed on the box label (see also Figure 51)

Table 25. Device Identification

	Trace Code marked on device	Internal Sales Type on box label
Flash Devices:	"XXXXXXXXXX"	7FSCRxxxx\$M1 7FSCRxxxx\$T1

19 REFERENCE SPECIFICATION

ST7SCR Datasheet 1.3 (March 2003).

20 SILICON LIMITATIONS

20.1 UNEXPECTED RESET FETCH

If an interrupt request occurs while a "POP CC" instruction is executed, the interrupt controller does not recognise the source of the interrupt and, by default, passes the RESET vector address to the CPU.

To solve this issue, a "POP CC" instruction must always be preceded by a "SIM" instruction.

20.2 USB: TWO CONSECUTIVE SETUP TOKENS

Description

When two consecutive SETUP tokens are received and the software does not have time to write the value 8 in the Endpoint 0 Reception Counter Register (CNT0RXR), the data associated with the second SETUP are not copied to the buffer.

Impact

The impact depends on the host behaviour. In the USB Spec 2.0 it is stated (chapter 5.5.5 p43) that: "A Setup transaction should not normally be sent before the completion of a previous control transfer. However, if a transfer is aborted, for example, due to errors on the bus, the host can send the next Setup transaction prematurely from the endpoint's perspective". If the new Setup token is sent because an error occurs in the previous one, it should contain the same data so no application malfunction will occur.

This limitation will be corrected in the next silicon revision. In the new revision, when a SETUP token is received, the value loaded in the internal counter is fixed to 8 by hardware independently of the value in the CNT0RXR register.

20.3 USB BUFFER SHARED MEMORY ACCESS

Description

When f_{CPU} is at 4 MHz, a value written in the USB buffer may be corrupted when V_{DD} is less than 4.4V. This limitation will be corrected in the next silicon revision.

Impact

USB buffer access cannot be guaranteed over the full V_{DD} range when f_{CPU} is at 4 MHz.

20.4 WDG (WATCHDOG) LIMITATIONS

In flash devices, the WDG prescaler value is not 65536 as described in Section 12.1.3 on page 40 (Figure 25), it is actually 16.

This will be corrected in the next revision of the silicon.

20.5 SUPPLY CURRENT IN HALT MODE (SUSPEND) LIMITATIONS

The current consumption (I_{DD}) in some devices may exceed the maximum specified in the documentation (up to 1mA).

Workaround

Declare 200mA max. power value in the USB Configuration Descriptor.

20.5.1 V_{PP} Pin Limitation

In the impacted flash devices, contrary to the datasheet specification (which specifies that it must be tied to V_{SS}), the V_{PP} pin must be tied to V_{DD} in operating mode. This will be fixed in the next silicon revision .

20.6 START-UP

The ST7SCR relies on internal LVD and it may not start-up correctly if the power supply is slow.

Workaround

Put a 1M Ω resistor between V_{DD} and V_{SS} to eliminate the offset on V_{DD} that may cause this power-on problem.

20.7 I/O PORT INPUT HIGH LEVEL (V_{IH})

The V_{IH} min value is $0.8 \cdot V_{DD}$ and not $0.7 \cdot V_{DD}$ as specified for the final silicon.

21 DEVICE MARKING

Figure 51. Revision Marking on Box Label and Device Marking

22 ERRATA SHEET REVISION HISTORY

Revision	Main Changes	Date
1.2	Updated Section 20.5 "SUPPLY CURRENT IN HALT MODE (SUSPEND) Limitations" on page 100 Added Section 20.6 "Start-UP" on page 100	03/13/03
