TDA7330B TDA7330BD

DESCRIPTION

The TDA7330B is a RDS demodulator. It recovers the additional inaudible RDS information which is transmitted by FM radio broadcasting stations.
The output data signal (RDDA) and clock signal (RDCL) can be further processed by a suitable RDS decoder (microprocessor).
The device operates in accordance with the EBU (European Broadcasting Union) specifications.
The IC includes a 2nd order antialiasing input filter, a 57KHz switched capacitor band pass filter, a smoothing filter and cross detector, a bit rate clock recovery circuit, a 57KHz PLL, BI-PHASE PSK decoder, differential decoding circuit, ARI indication and RDS signal quality output.

OUTPUT TIMING

The generated 1187.5Hz output clock (RDCL line) is synchronized to the incoming data.
According to the internal PLL lock condition this data change can results on the falling or on the rising clock edge.
Whichever clock edge is used by the decoder (rising or falling edge) the data will remain valid for 416.7 µsec after the clock transition.

APPLICATION SUGGESTION

- A good DC decoupling between V_{CC} and GROUND is necessary: a 100nF ceramic capacitor, with low resistance and low inductance at high frequency, directly connected on pin 16 (V_{CC})and 5 (GND) is recommended.
- A small series inductance (100µH) or resistor (27Ω) may be used for supply line filtering.
- The Layout path pin2 - C2 - pin5 must be as short as possible.
- If the supply line, after the power on has a soft and disturbed (spikes) slope, a capacitor of 100nF, between POR and V_{CC}, is racommended.
- The various testing pins have no sense for the customer.
