

DIGITALLY CONTROLLED AUDIO PROCESSOR WITH SURROUND SOUND MATRIX

- 1 STEREO INPUT
- VOLUME CONTROL IN 1.25dB STEP
- TREBLE AND BASS CONTROL
- THREE SURROUND MODES ARE AVAIL-ABLE:
 - MOVIE, MUSIC AND SIMULATED
- FOUR SPEAKER ATTENUATORS:
 4 INDEPENDENT SPEAKERS CONTROL IN 1.25dB STEPS FOR BALANCE FACILITY
 INDEPENDENT MUTE FUNCTION
- ALL FUNCTIONS PROGRAMMABLE VIA SE-RIAL BUS

DESCRIPTION

PIN CONNECTION

The TDA7345 is a volume tone (bass and treble) balance (Left/Right) processor for quality audio applications in car radio and Hi-Fi systems.

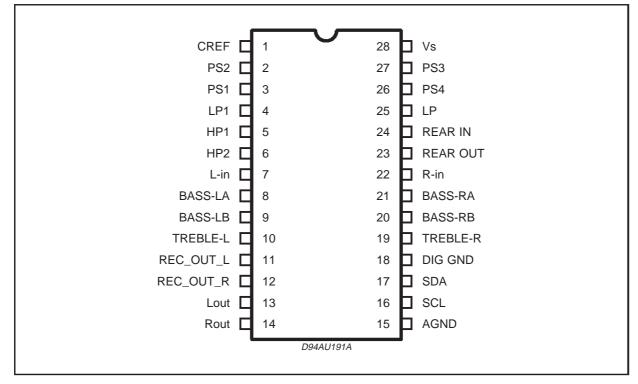

It reproduces surround sound by using phase shifters and a signal matrix. Control of all the functions is accomplished by serial bus.

The AC signal setting is obtained by resistor net-

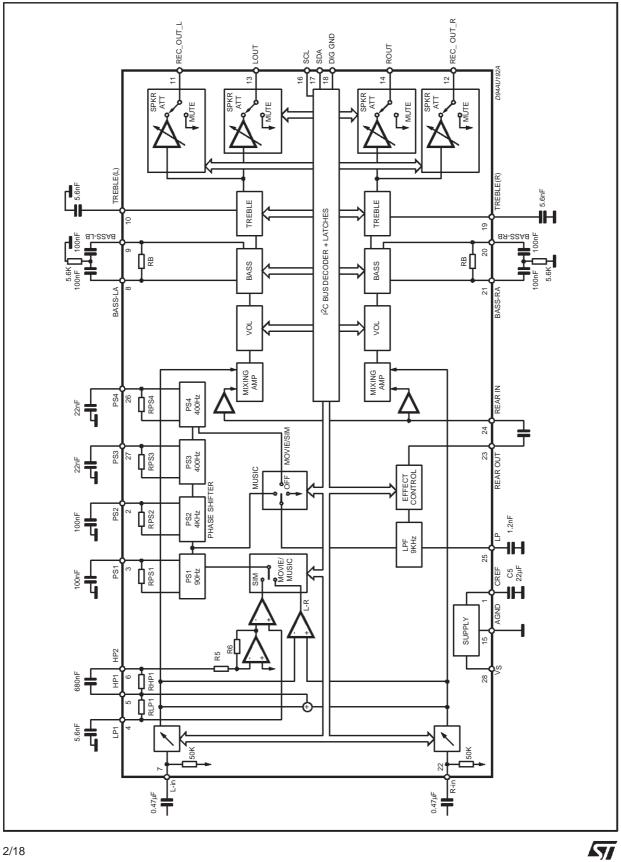

works and switches combined with operational amplifiers.

Thanks to the used BIPOLAR/CMOS Technology, Low Distortion, Low Noise and DC stepping are obtained.

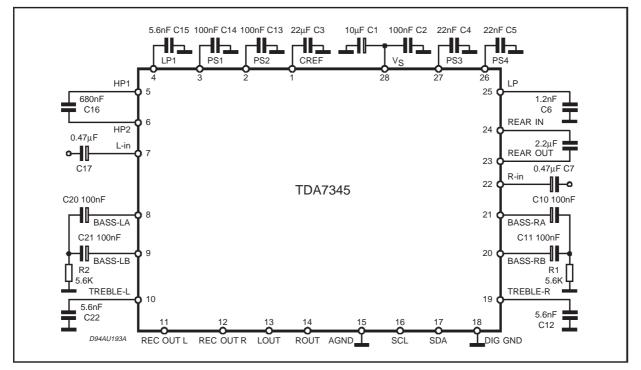

November 1999

Note:

(1) Bass and Treble response: The center frequency and the resonance quality can be choosen by the external circuitry. A standard first order bass response can be realized by a standard feedback network.

(2) The peack voltage of the two input signals must be less then $\frac{V_s}{2}$:

dB

¹²C BUS INTERFACE

Data transmission from microprocessor to the TDA7345 and viceversa takes place through the 2 wires I^2C BUS interface, consisting of the two lines SDA and SCL (pull-up resistors to positive supply voltage must be connected).

Data Validity

As shown in fig. 3, the data on the SDA line must be stable during the high period of the clock. The HIGH and LOW state of the data line can only change when the clock signal on the SCL line is LOW.

Start and Stop Conditions

As shown in fig.4 a start condition is a HIGH to LOW transition of the SDA line while SCL is HIGH. The stop condition is a LOW to HIGH transition of the SDA line while SCL is HIGH.

Byte Format

Every byte transferred on the SDA line must contain 8 bits. Each byte must be followed by an ac-

Figure 3: Data Validity on the I²CBUS

knowledge bit. The MSB is transferred first.

Acknowledge

The master (μ P) puts a resistive HIGH level on the SDA line during the acknowledge clock pulse (see fig. 5). The peripheral (audioprocessor) that acknowledges has to pull-down (LOW) the SDA line during the acknowledge clock pulse, so that the SDA line is stable LOW during this clock pulse.

The audioprocessor which has been addressed has to generate an acknowledge after the reception of each byte, otherwise the SDA line remains at the HIGH level during the ninth clock pulse time. In this case the master transmitter can generate the STOP information in order to abort the transfer.

Transmission without Acknowledge

Avoiding to detect the acknowledge of the audioprocessor, the μ P can use a simpler transmission: simply it waits one clock without checking the slave acknowledging, and sends the new data.

This approach of course is less protected from misworking and decreases the noise immunity.

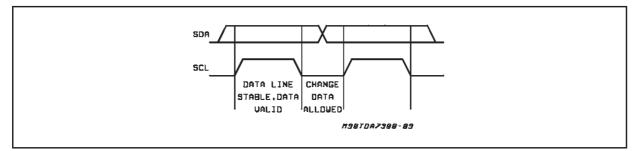

Figure 4: Timing Diagram of I²CBUS

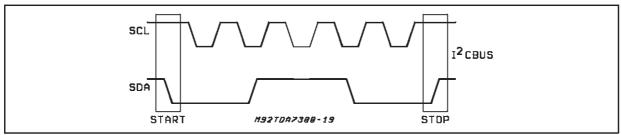

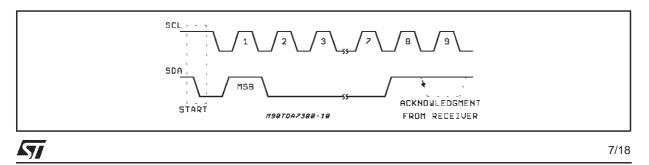

Figure 5: Acknowledge on the I²CBUS

SOFTWARE SPECIFICATION

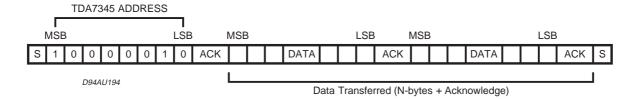

Interface Protocol

The interface protocol comprises:

- A start condition (s)
- A chip address byte, containing the TDA7345 address (the 8th bit of the byte must be 0).
 The TDA7345 must always acknowledge at

the end of each transmitted byte.

- A subaddress (function) bytes (identified by the MSB = 0)
- A sequence of dates and subaddresses (N bytes + achnowledge. The dates are identified by MSB = 1, subaddresses by MSB = 0)
- A stop condition (P)

ACK = Achnowledge S = Start

P = Stop

INTERFACE FEATURES

- Due to the fact that the MSB is used to select if the byte transmitted is a subaddress (function) or a data (value), between a start and stop condition, is possible to receive, how many subaddresses and datas as wanted.
- The subaddress (function) is fixed until a new subaddress is transmitted, so the TDA7345 can receive how many data as wanted for the selected subaddress (without the need for a new start condition)
- If TDA7345 receives a subaddress with the LSB = 1 the incremental bus is selected, so it enters in a loop condition that means that every acknowledge will increase automatically the subaddress (function) and it receives the data related to the new subaddress.

EXAMPLES

1) NO INCREMENTAL BUS

TDA7345 receives a start condition, the correct

chip address, a subaddress with the LSB = 0 (no incremental bus), N-datas (all these datas concern the subaddress selected), a new subaddress, N-data, a stop condition.

So it can receive in a single transmission how many subaddress are necessary, and for each subaddress how many data are necessary.

2) INCREMENTAL BUS

TDA7345 receives a start condition, the correct chip address a subaddress with the LSB = 1 (incremental bus): now it is in a loop condition with an autoincrease of the subaddress.

The first data that it receives doesn't concern the subaddress sended but the next one, the second one concerns the subaddress sended plus two in the loop etc, and at the end it receives the stop condition.

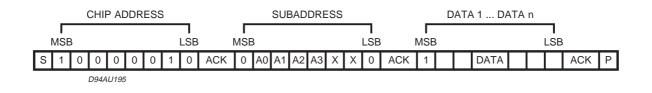

In the pictures there are some examples:

ACK = acknowledge

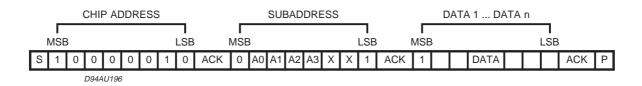

B = 1 incremental bus, B = 0 no incremental bus P = stop

<u>ل</u>حک

1) one subaddress, with n data concerning that subaddress (no incremental bus)

2) one subaddress, (with incremental bus), with n data (data1 that concerns subaddress +1, data 2 that concerns subaddress + 2 etc.)

3) more subaddress with more data

DATA BYTES FUNCTION SELECTION FIRST BYTE (subaddress)

The first byte select the function, it is identified by the MSB = 0
